# What Does a Unified Dial Plan Look Like?

**William Bell,  
Chesapeake Netcraftsmen**

**[wjb@netcraftsmen.net](mailto:wjb@netcraftsmen.net)**

**October, 2009**

# Agenda

- **Dial Plan Elements Overview**

*An introduction to basic elements of the Cisco Unified Communications Manager (CUCM) solution*

- **Evolution of a Dial Plan**

*Using real situations as examples, we will touch on issues with some common dial plan implementations and how architectures must evolve*

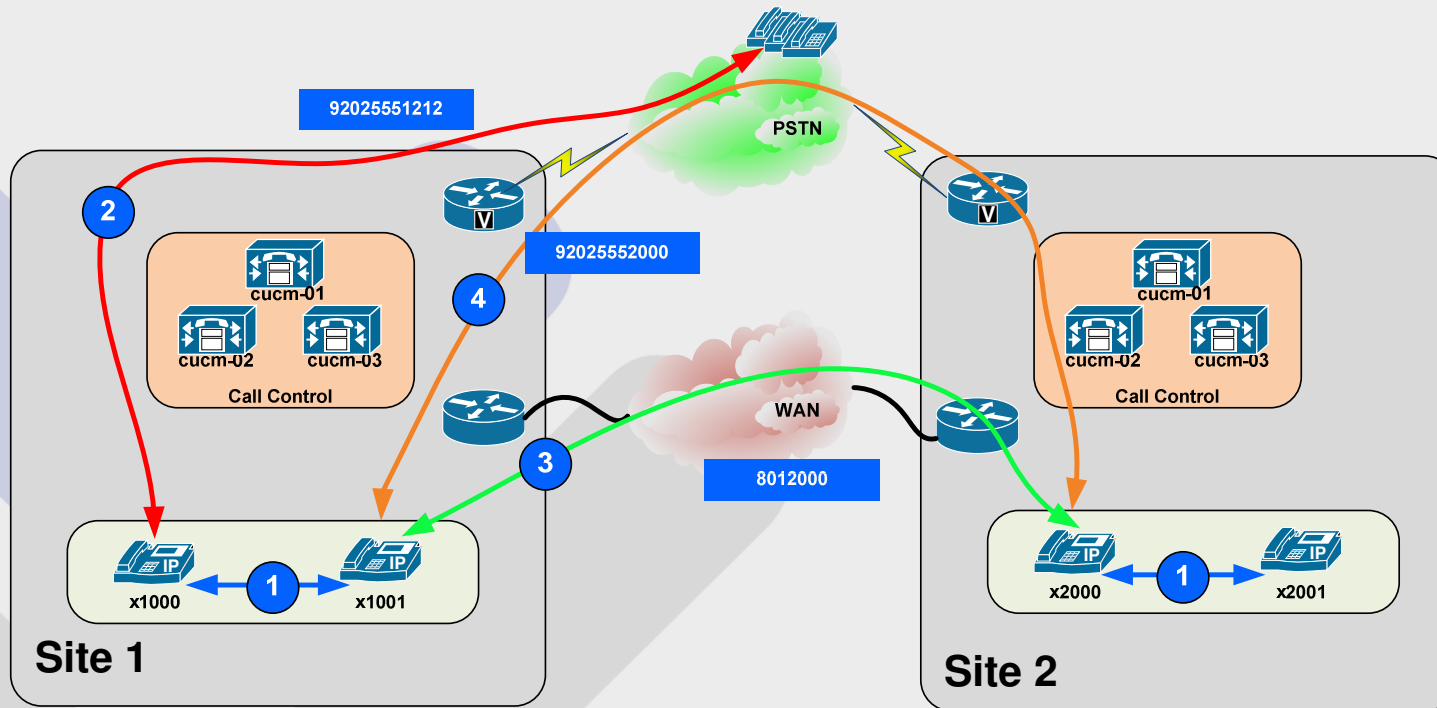

- **Dial Plan Changes in CUCM 7x**

*Significant features have been introduced with CUCM 7x that facilitate greater adaptability and scalability within a dial plan*

# Dial Plan Basics

**The Cliff Notes Version**

# Call Types and Routing

- 1 OnNet/IntraCluster:** Destination directory number (DN) is registered with local CUCM cluster
- 2 OffNet:** DN is routed through PSTN
- 3 InterCluster:** DN exists on another CUCM cluster
- 4 Alternate Routing:** Allowing calls to follow alternate paths

# Digit Analysis: Patterns

Pattern	Description	Example
0,1,2,3,4,5,6,7,8,9,*,#	Match exactly one keypad button	
X	Any single digit 0-9	72XX matches 7200 to 7299
[xyz]	Exactly one of any KP buttons in brackets	7[2468]00 matches 7200, 7400, 7600, 7800
[x-z]	Exactly one of any digit between x and z, inclusive	7[2-5]00 matches 7200, 7300, 7400, 7500
[^x-z]	Any digit that is <b>NOT</b> between x and z, inclusive	7[^2-8]00 matches 7000, 7100, 7900
!	One or more digits in the range of 0-9	9! Matches 91, 9123, 91234, 912345678123
?	Matches zero or more occurrences of previous digit	91?4105551212 matches 94105551212, 914105551212
+	Matches one or more occurrences of previous digit	91+ matches 91, 911, 9111, 91111
\+	The + also is a special character in CUCM 7.x that is used for e.164 dialing strings	+14105551212 is the e.164 number for station in 410 NPA of the NANP
@	Numbering plan macro	9.@

# Digit Analysis: More Examples

*2000	An exact match for pattern *2000 (asterisk is a digit!)
2XXX#	Any pattern 2000# to 2999# (the # has to be dialed)
9.911	Matches 9911, the dot "." is used for digit manipulation
9.1[2-9]XX[2-9]XXXXXX	Matches long distance dialing strings in NANP
9.[2-8]11	Matches PSTN service codes in NANP
9.[^19]11	Same as above, though less intuitive
9.011!	International dialing prefix for North America, will match any number of digits after the 011 (e.g. 9.011330856778)
1[2-5]6[189]X	Matches 12610, 12611, 15689, etc.
1[^16789]6[^0234567]X	<b>Invalid.</b> Only one circumflex character is allowed per string
<blank>	Meaning no digits. This is allowed, and will be an immediate match/route. A PLAR like application
9.1?410[2-9]XXXXXX	Matches 94105551212, 914105551212, and 91111111114105551212 – yeah, that's right
\+!	New in CUCM 7x, matches any e.164 number string

# Digit Analysis: Pattern Types

Pattern Type	Description
<b>Device (Directory Number)</b>	Pattern assigned to station line on IP phone, CTI Port, CTI Route Point
<b>Route Pattern</b>	Pattern used to send calls to any Off Cluster location
<b>Translation Pattern</b>	Similar to Route Patterns in form and function but keeps call On Cluster
<b>Voicemail Port</b>	Pattern assigned to voicemail port
<b>Message Waiting</b>	Pattern used by voicemail applications to toggle MWI
<b>Hunt Pilot</b>	Patterns used to direct callers to hunt groups/line groups
<b>Call Pickup</b>	Patterns that “link” line DNs together and allow users to grab a call to any DN in their pickup group
<b>Call Park / Directed Call Park</b>	Patterns that allow users to place callers on hold in a way that can be retrieved by another phone line
<b>Intercom</b>	Like DNs but application specific pattern for intercom
<b>Intercom Translations</b>	Like translation but applied to intercom configs only

# Digit Analysis: Pattern Types (2)

Pattern Type	Description
<b>Conference</b>	Meet me line numbers that users can leverage to open up multi-party conference lines
<b>Voicemail Pilot</b>	Pilot numbers that are used to control routing of 'messages' button and allow easier admin of call forwarding to VM
<b>Transformation Patterns</b>	Used to normalize calling party information when presented to end station. Objective is to minimize need for called user to manipulate digits on return calls
<b>Application Dial Rules</b>	Used by applications like Click-to-call widget, CUCM Assistant, and Web Dialer to manipulate digits to conform to dial plan
<b>Directory Lookup Dial Rules</b>	Used by Attendant Console application to assist in mapping an existing directory name to calling party number
<b>SIP Dial Rules</b>	Used by SIP end points (line side) to enable SIP phones to be "aware" of the basic dial plan rules of the CUCM cluster and process user digits efficiently

# Digit Analysis: Process Example

**User Action: <offhook>**

## CUCM Actions:

- Provide Dial Tone
- Wait for “Off Hook to First Digit” timeout

With “!” there are  $\infty$  number of matches. However, CUCM only looks at potential matches given number of digits dialed!

# Partitions and Calling Search Spaces

- Patterns are given **context** with Partitions and Calling Search Spaces (CSS)
- A Partition (PT) is a container that holds patterns
- A CSS is a container that holds Partitions

# Partitions and Calling Search Spaces

CSS is assigned to any object that can **Originate** or **Redirect** a call setup

## Phones

CSS: CSS1

# Digit Analysis: CSS+Partitions

## Longest Match Wins!

No matter what the partition order is, the longest digit match wins!

CSS: MyPhone\_CSS    User Dials: **8211**

P1	A_PT	8[23]XX	911	9.011!#
P2	B_PT	85XX	8211	8311
P3	C_PT	8[23]XX	9.[2-9]XX[2-9]XXXXXX	

## Partition Priority Determines Tie Breaker!

If two patterns present an identical match, then partition priority plays a role

CSS: MyPhone\_CSS    User Dials: **8277**

P1	A_PT	8[23]XX	911	9.011!#
P2	B_PT	85XX	8211	8311
P3	C_PT	8[23]XX	9.[2-9]XX[2-9]XXXXXX	

## Line CSS and Device CSS are additive!

The effective CSS when a user goes off hook to call is the concatenation of the line level CSS and device level CSS. Notice what happens now when we dial 8277.

Device CSS	
CSS:	CSS1
A_PT	
B_PT	
Line CSS	
CSS:	CSS2
C_PT	

CSS: Effective CSS    User Dials: **8277**

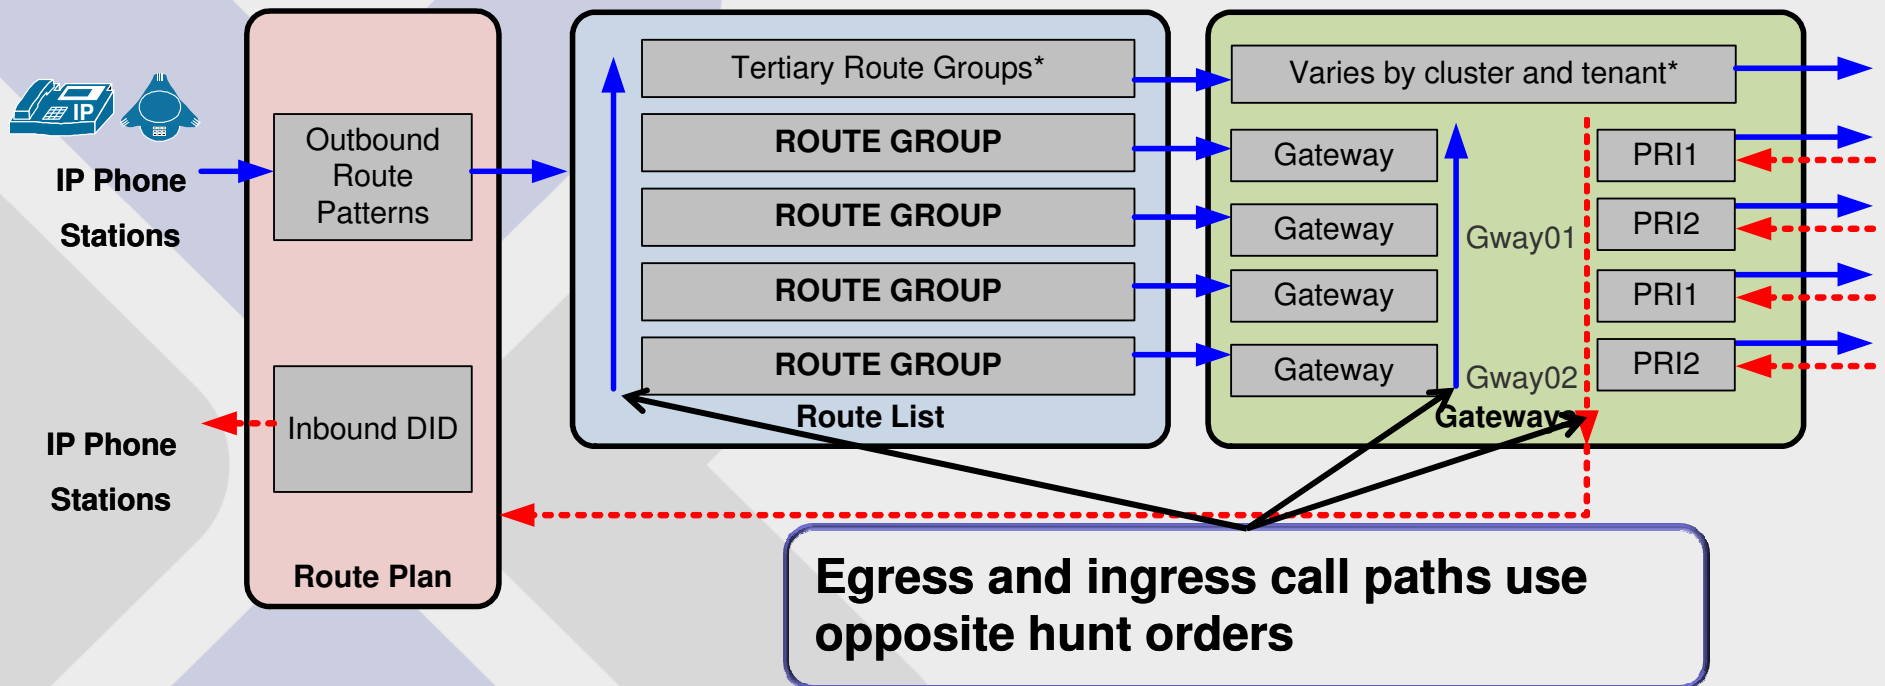

P1	C_PT	8[23]XX	9.[2-9]XX[2-9]XXXXXX	
P2	A_PT	8[23]XX	911	9.011!#
P3	B_PT	85XX	8211	8311

# <none>

- There is a special route partition: <none>
  - <none> PT is visible from all Calling Search Spaces
- There is a special CSS: <none>
  - <none> CSS contains only the <none> PT
- Using the <none> partition can lead to unexpected call routing behavior
- Mixing <none> CSS and partitions is living on borrowed time
- Note that in pre-6x releases, having a Call Forward All (CFA) CSS of <none> would cause the CUCM forwarding engine to use the calling party's CSS to route the call

# I Found a Match, Now What?

- Route Patterns use Route Lists (RL) to start selecting a call path (traditional)
- Route Lists contain Route Groups (RG)

- Features in CUCM 7x will be discussed later

# The Evolution of a Dial Plan

***Everything should be made as simple as possible, but not simpler.***

# Case Studies

- **Case Study: Class of Restriction (COR)**

*Device Level vs. Line Level COR options, the first evolution taken by Cisco in their “advanced dial plan” education series*

- **Case Study: Multi-tenant Dial Plan**

*What happens when you must provide different tenant groups completely different abbreviated dialing solutions in a non-uniform dial plan*

- **Case Study: Dial Plan Hierarchy**

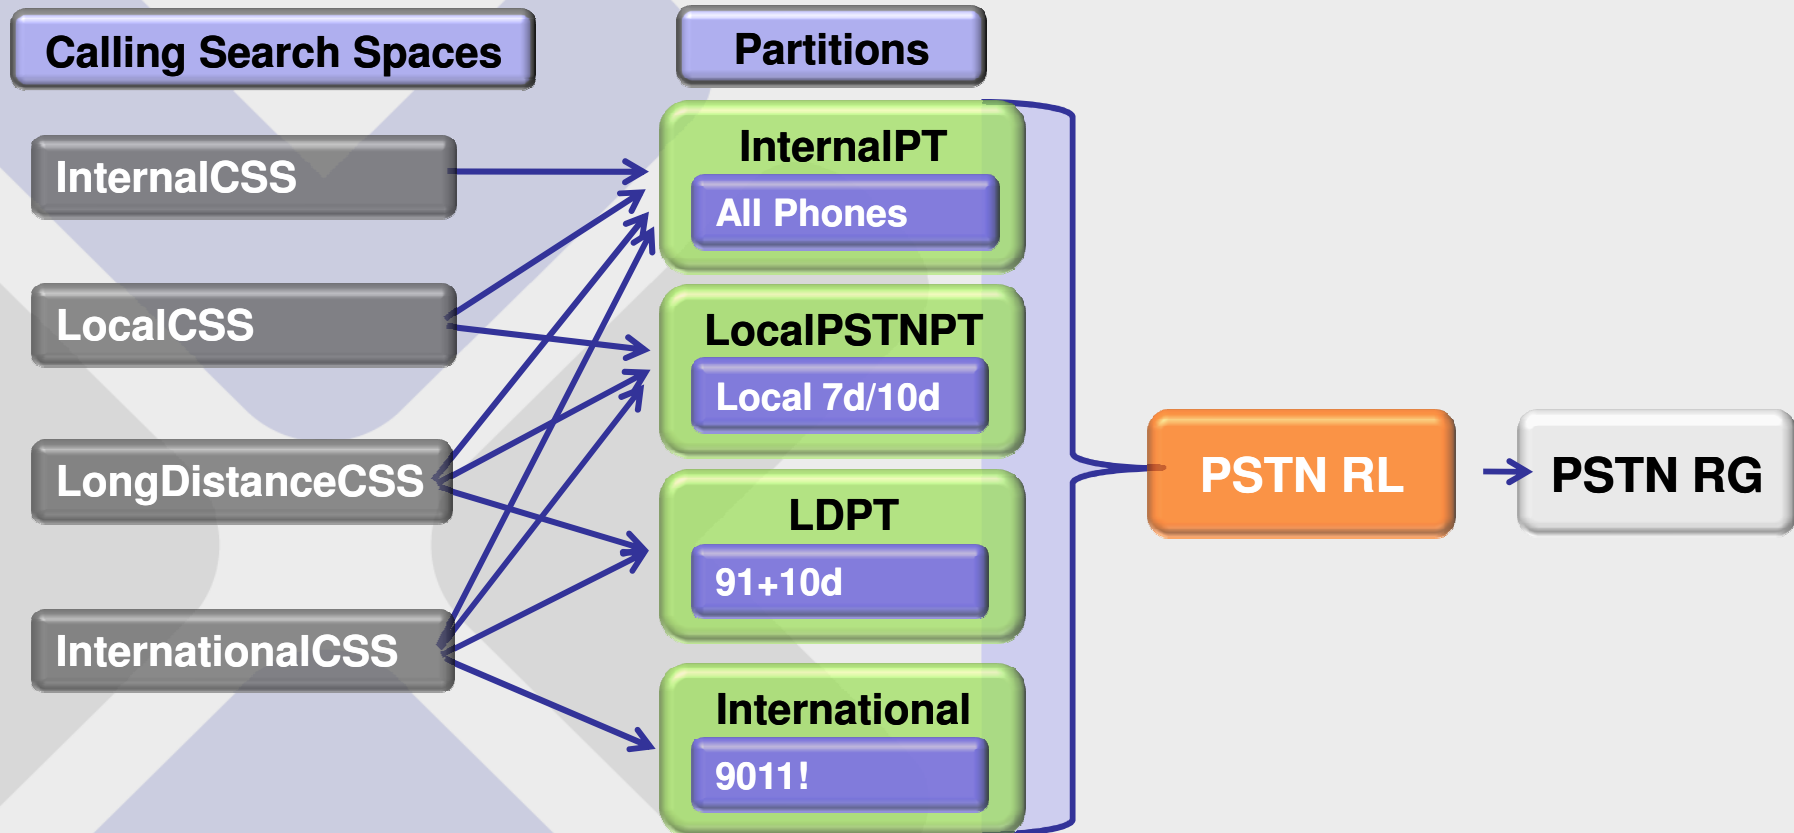

*Why should one try to put some structure into their dial plan design*

# Evolution of a Dial Plan

## Case Study: Class of Restriction (COR)

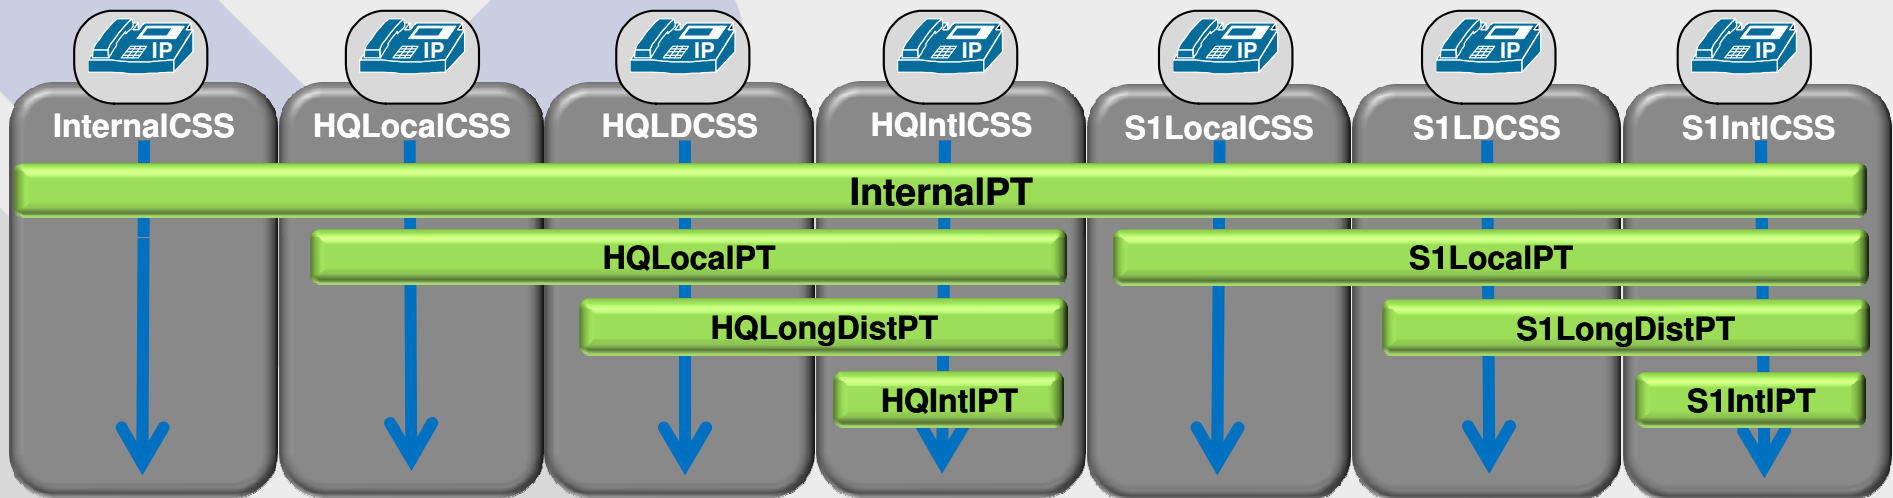

# A Case Study: Class of Restriction (COR)

The traditional Class of Restriction approach was to implicitly “block” access to digit patterns by creating COR classes which only included what a user could dial.

# A Case Study: Class of Restriction (COR)

This may be fine for a deployment with one site, but what if you have multiple sites with different gateways, route groups, route lists?

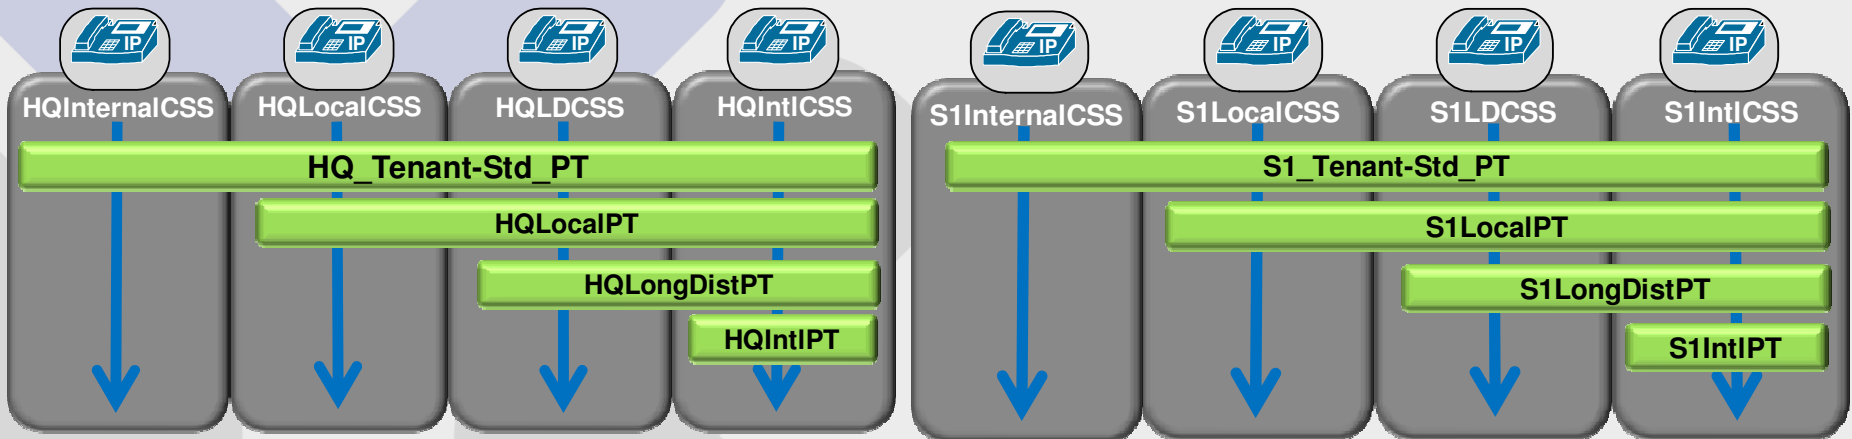

The CSS's required is a factor of  $N \text{ sites} * 3$  plus the InternalCSS used by all phones.

- 5 sites require 16 CSS configurations
- 10 sites require 31 CSS configurations

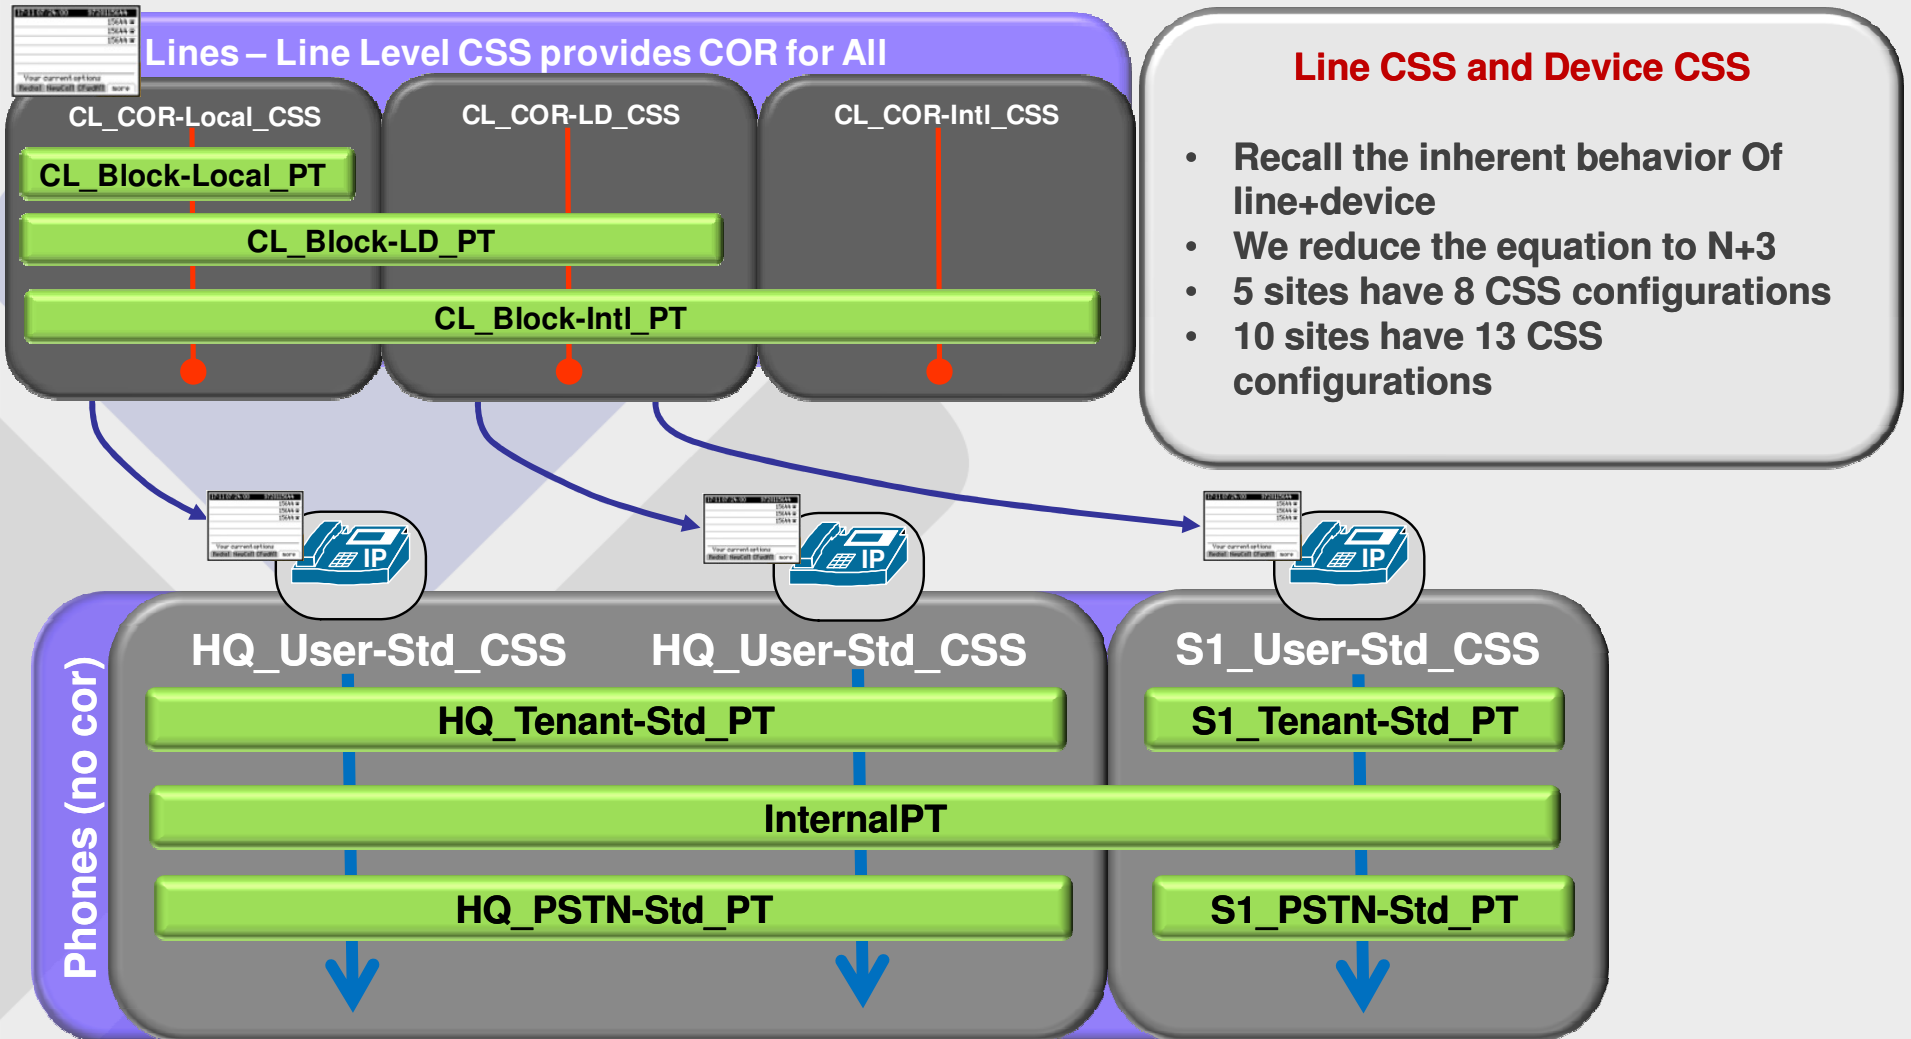

# A Case Study: Class of Restriction (COR)

What happens when you have a need to allow local sites to reach their office attendants by dialing “0”? Then you need to have an HQInternalPT and a S1InternalPT, along with the associated CSS. So, (N\*4) CSS’s are needed.

- A deployment with 5 sites has at least 20 CSS configurations
- A deployment with 10 sites has at least 40 CSS configurations
- **What about services that are shared across all sites?**
- **What if you wanted to add Forced Authorization Codes to this solution?**
- **What about Extension Mobility?**

# A Solution: Class of Restriction (COR)

# A Solution: Class of Restriction (COR)

## Line Level COR

CL\_COR-LD\_CSS

CL\_Block-LD\_PT

CL\_Block-Intl\_PT

## Extension Mobility

- User Device Profiles (UDP) are configured with lines
- A UDP line will override device lines when user logs on
- COR follows user profiles

HQ\_User-Std\_CSS

HQ\_Tenant-Std\_PT

# Evolution of a Dial Plan

## Case Study: Multi-tenant Dial Plan

# A Case Study: Multi-tenant Dial Plan

# A Solution: Multi-tenant Dial Plan

## Engineering

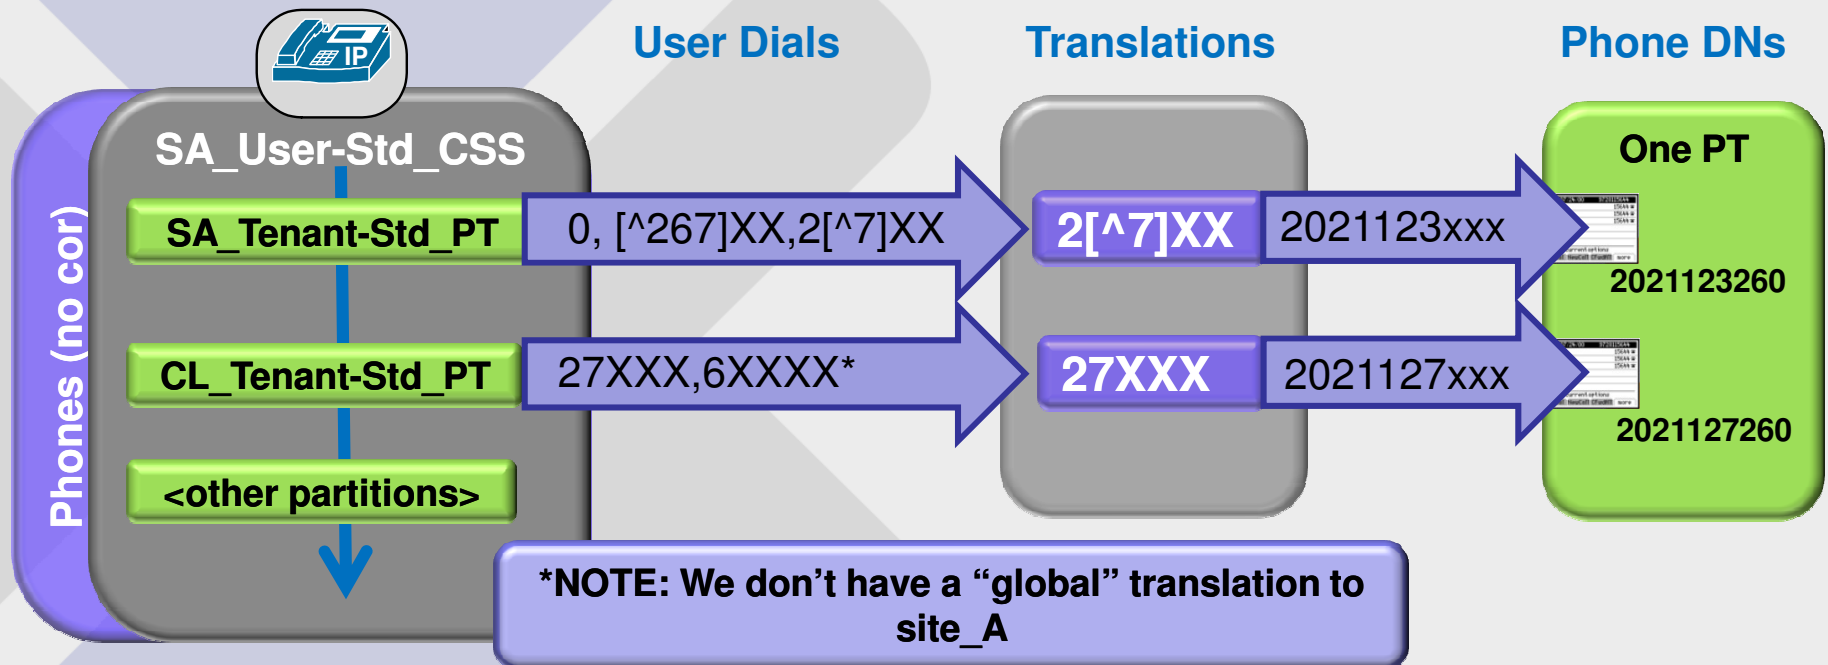

- Wants a uniform dial plan
- Wants to centralize services like VM
- Needs to interoperate with Centrex/PBX

## Future Challenges

## Business

- Wants to minimize impact on users
- Plans to keep expanding
- Minimize costs with centralized services

One Aspect of Solution: Variable Length OffNet Dialing (**VLOD**) with Flat Addressing

# A Solution: Multi-tenant Dial Plan

## The Ingredients

### Directory Number Digit Strings

Use a digit string standard that is guaranteed unique:

- Site code method 8**SSS**HHHH
- NANP method **NPANXX**HHHH
- E.164 method \+! (e.g. +14105551212)

### Directory Numbers Assign to a Single PT

Scalability for application features (e.g):

- Multi-tenant MWI
- Presence
- Time of Day routing

### DN Partition not Directly Visible from Calling Station

Required if you want to also support local abbreviated dialing translations and for other reasons

### Translation Patterns are Your Friend

Translations are handy tactical tools and **absolutely necessary** when building a modular and scalable dial plan design

# A Solution: Multi-tenant Dial Plan

## Handy Info

Use Line Labels to “trick” users

The Placed Calls directory will use what was dialed and not the translated pattern

Learn to use Dialed Number Analysis (DNA) tool

For “private” or “soft” extensions, consider using **leading digit** of 0 or 1 in the **NPA** or **NXX** field of a NANP number: these numbers are excluded from geographic or service assignment

## Other Considerations

Interoperability and exchanging Calling, Called, and Redirect party information with external systems like Voicemail, non-Cisco PBX, Intercluster trunk, and Centrex

Call origination points other than IP Phones (e.g. VM, Contact Center, PSTN)

Corporate Directory(ies)

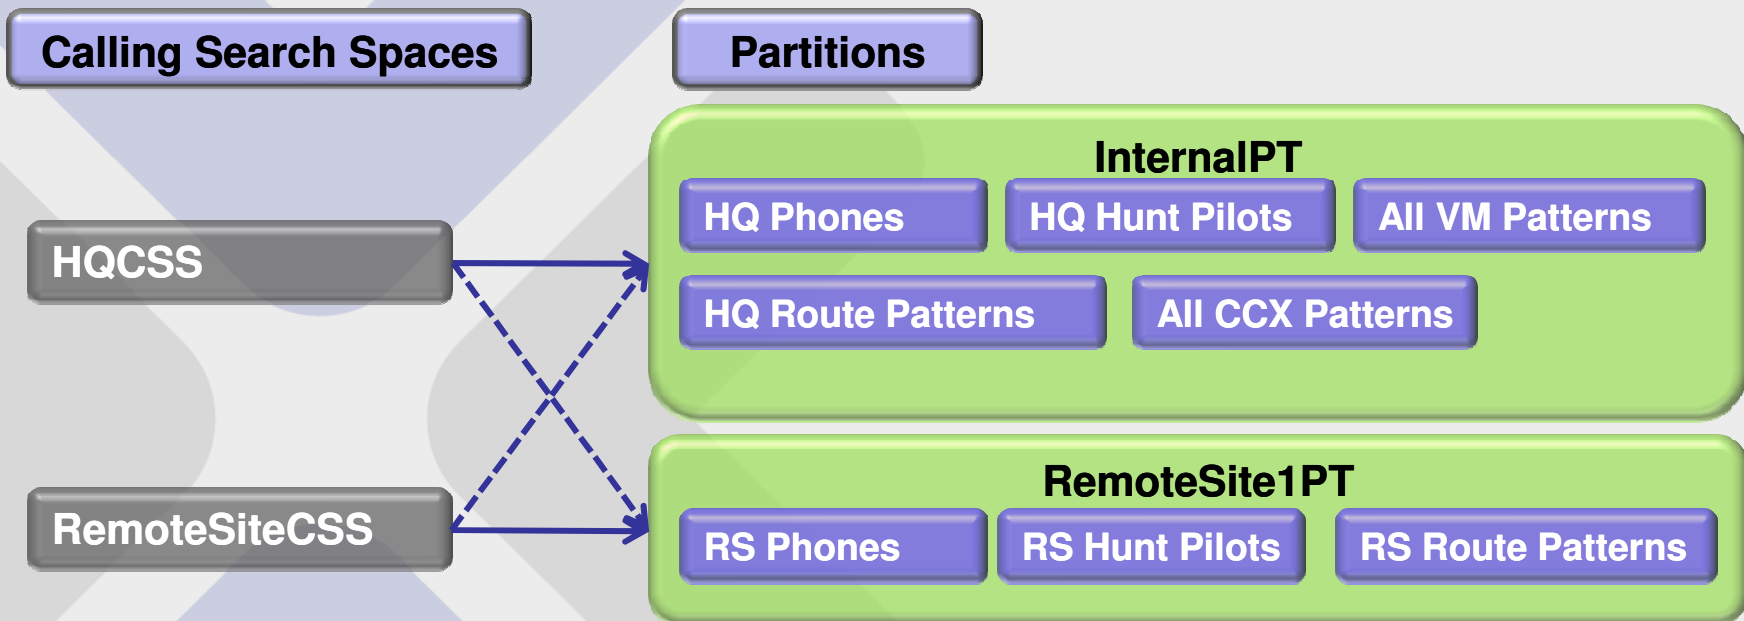

# Evolution of a Dial Plan

## Case Study: Dial Plan Hierarchy

# A Case Study: Dial Plan Hierarchy

Not a topic that gets adequate attention. Scenario: Each remote site has its own CSS and Partitions. Phones at a remote site are in RS PT but all sites can see all PTs. Finally, pattern types/functions are combined in same partitions.

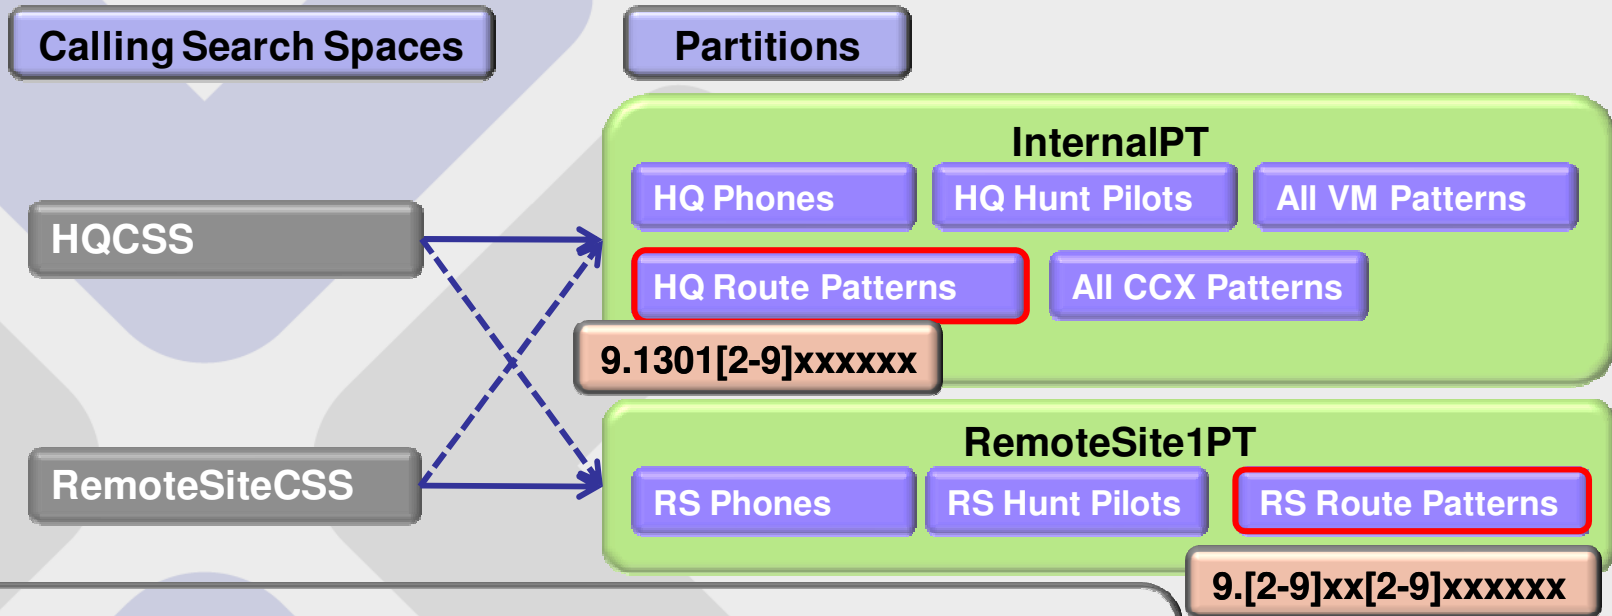

# A Case Study: Dial Plan Hierarchy

Why is this an issue?

There is potential overlapping with route patterns. Admin inadvertently adds a more specific pattern to allow callers with LD restriction to call 301 NPA in HQ.

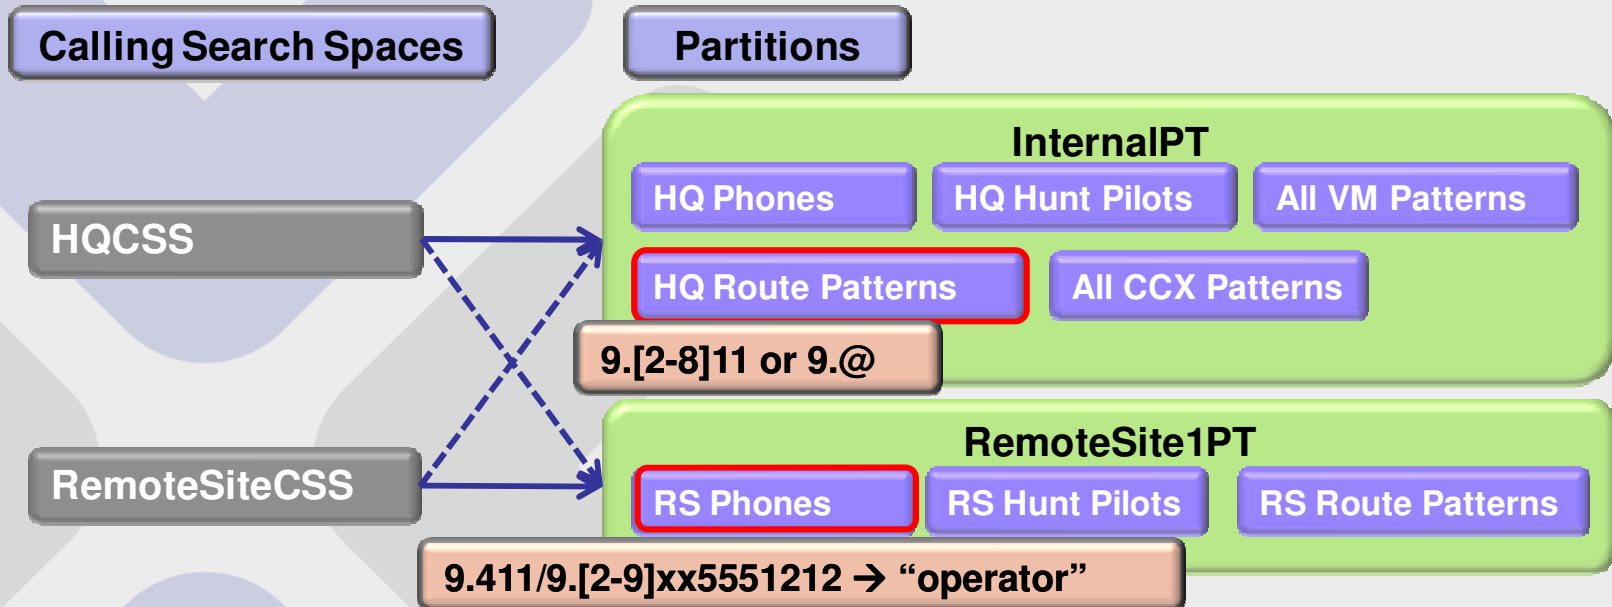

On the surface, it is nice to have a design which allows for a single configuration step to override “defaults”. But what if you had 5+ sites and you don’t want calls to start flowing to HQ for the 301 NPA?

# A Case Study: Dial Plan Hierarchy

Why is this an issue?

There is potential overlapping between pattern types. Admin wants a regional site's calls to 411 to route to internal operator to reduce "411" costs

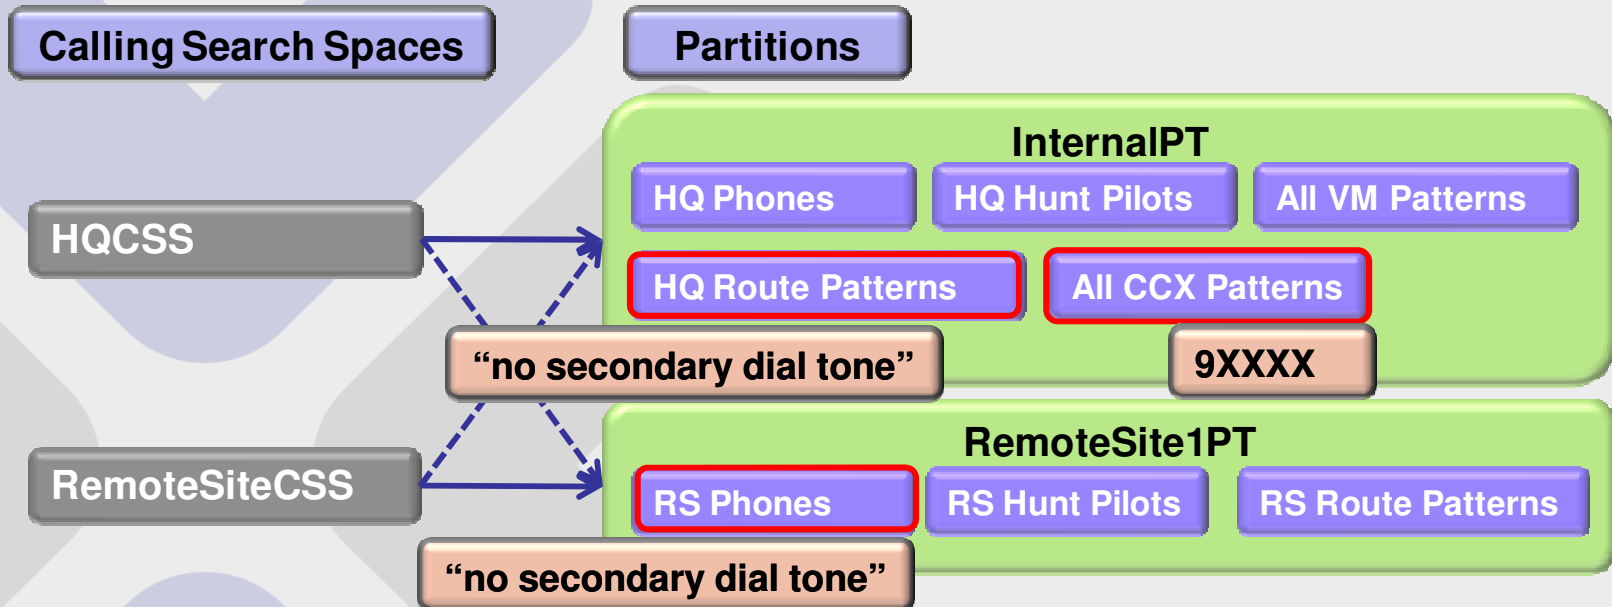

Calls to "411" from HQ now flow to remote site. Also, what happens when that internal operator needs to call "411" for any reason? What about other regional sites?

# A Case Study: Dial Plan Hierarchy

Why is this an issue?

Configurations on an application may affect the end user community? Admin decided to use “non-DID” range of 9XXXX for CCX ports.

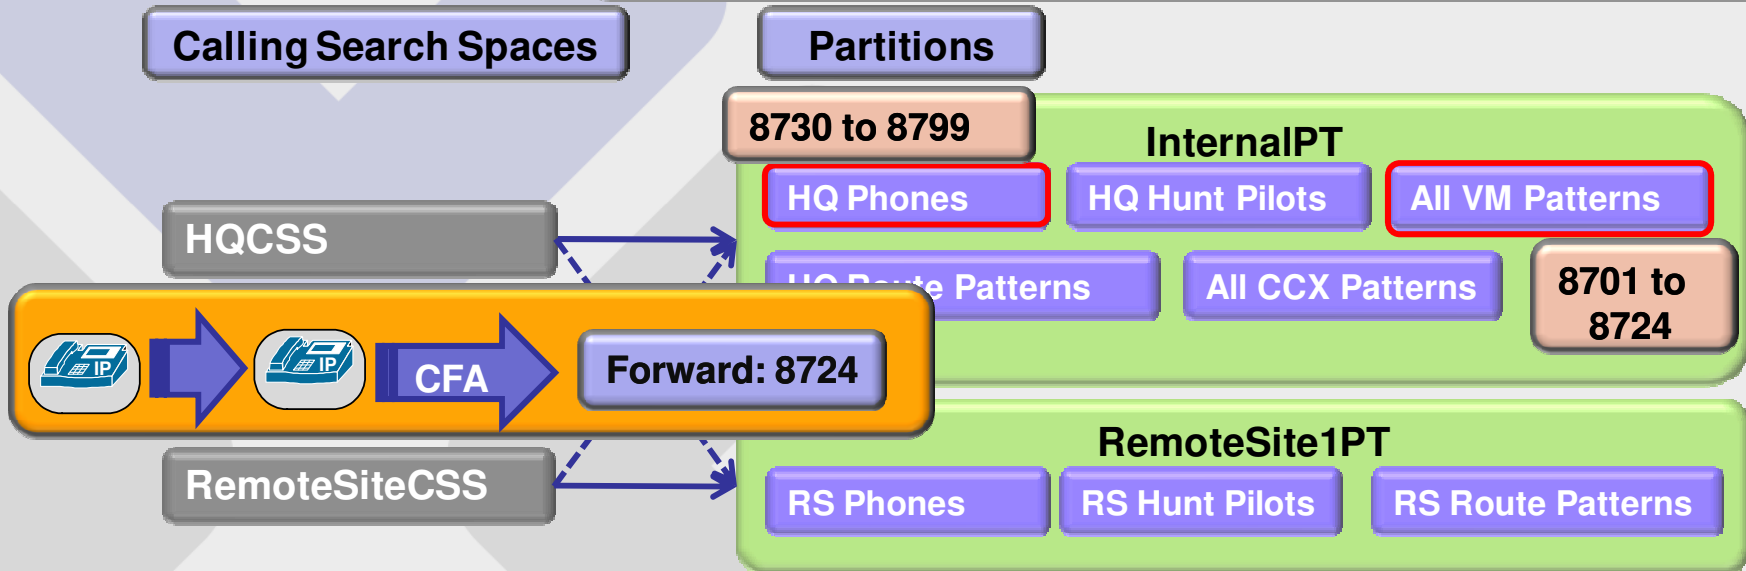

Secondary dial tone is provided by CUCM when all patterns that match a dial digit have this option checked. This option is only available on Route Patterns and translations.

# A Case Study: Dial Plan Hierarchy

Why is this an issue?

Configurations for end users may negatively impact applications. Customer has Unity with failover and has secondary Unity configured to fail immediate on receiving calls.

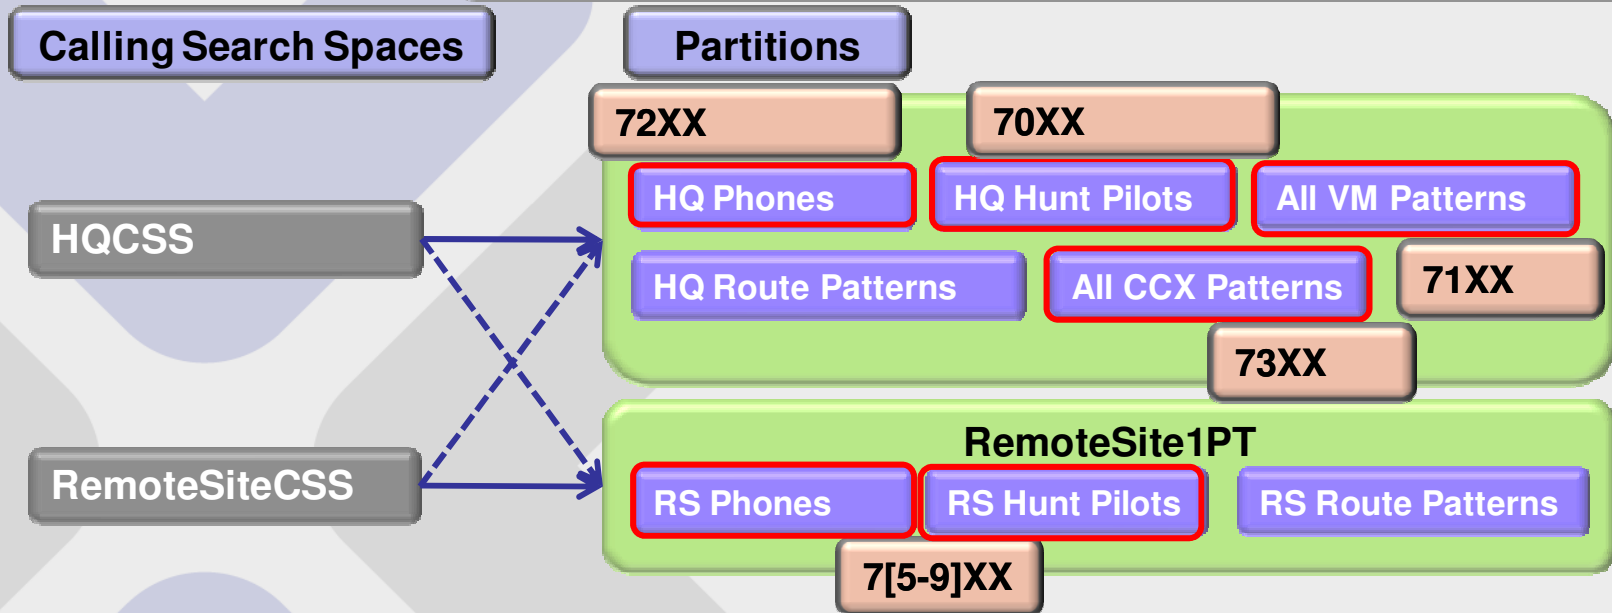

User accidentally forwards calls to 8724 (instead of 8754) and admin reports intermittent Unity failures in the middle of the day. Something must be wrong with CUCM or Unity, right??

# A Case Study: Dial Plan Hierarchy

Why is this an issue?

On initial build, admin thought that 7XXX would never be a supported DID range and assigned this as an “internal” extension range. Then one day, a new site comes on and 0xxx, 7xxx, and 9xxx are all that is available.

There are options, but just like this slide, none are pretty and all require some heavy lifting.

# Solution: Dial Plan Hierarchy

At some point in time a dial plan solution has to be more than pushing digits between plastic. It should **enable** the business, **not restrict** it.

## First Step: Define Objectives

Meet existing population needs and support growth

Must account for the most complex scenario for any given component

Segmentation of users, applications, and components

Scalable

Consistent

Address security requirements at a system and tenant level

Modular

Secure

Adaptable

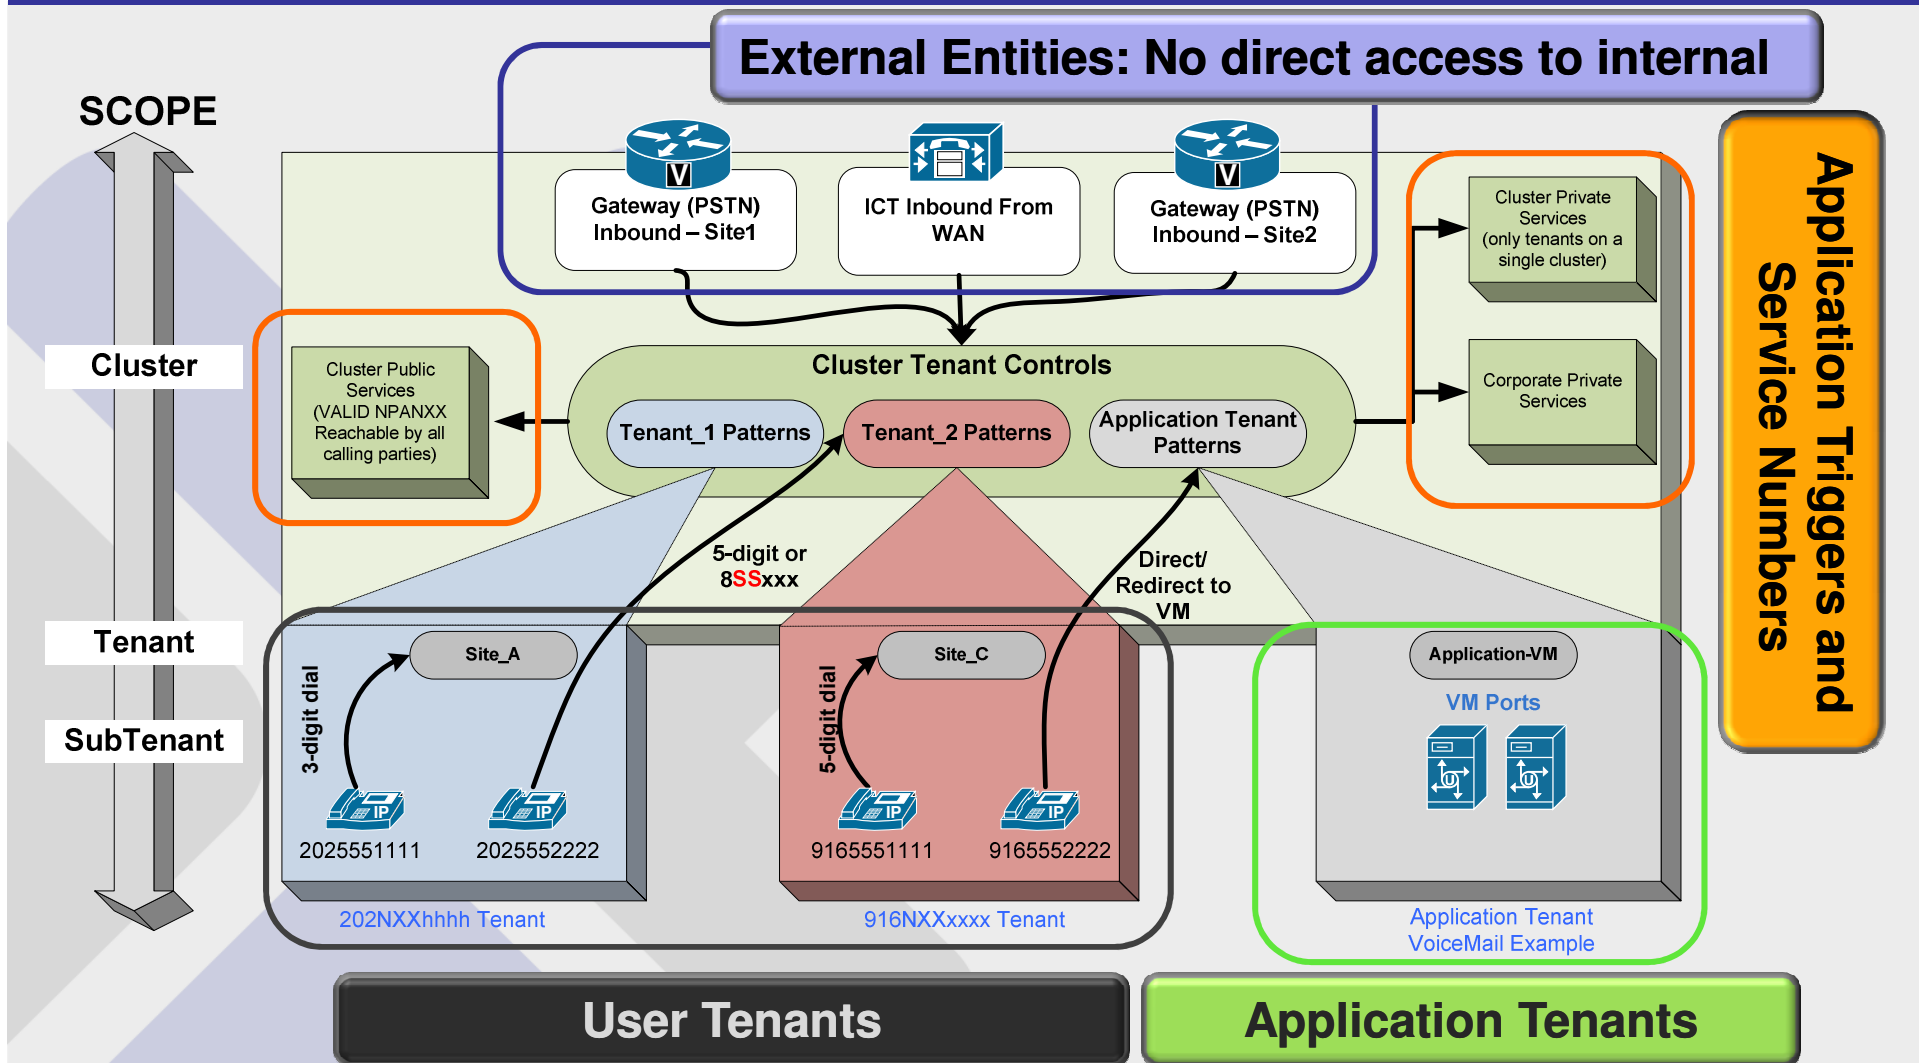

Supportable

Ability to quickly adapt to changing business needs

Facilitate easier maintenance and troubleshooting

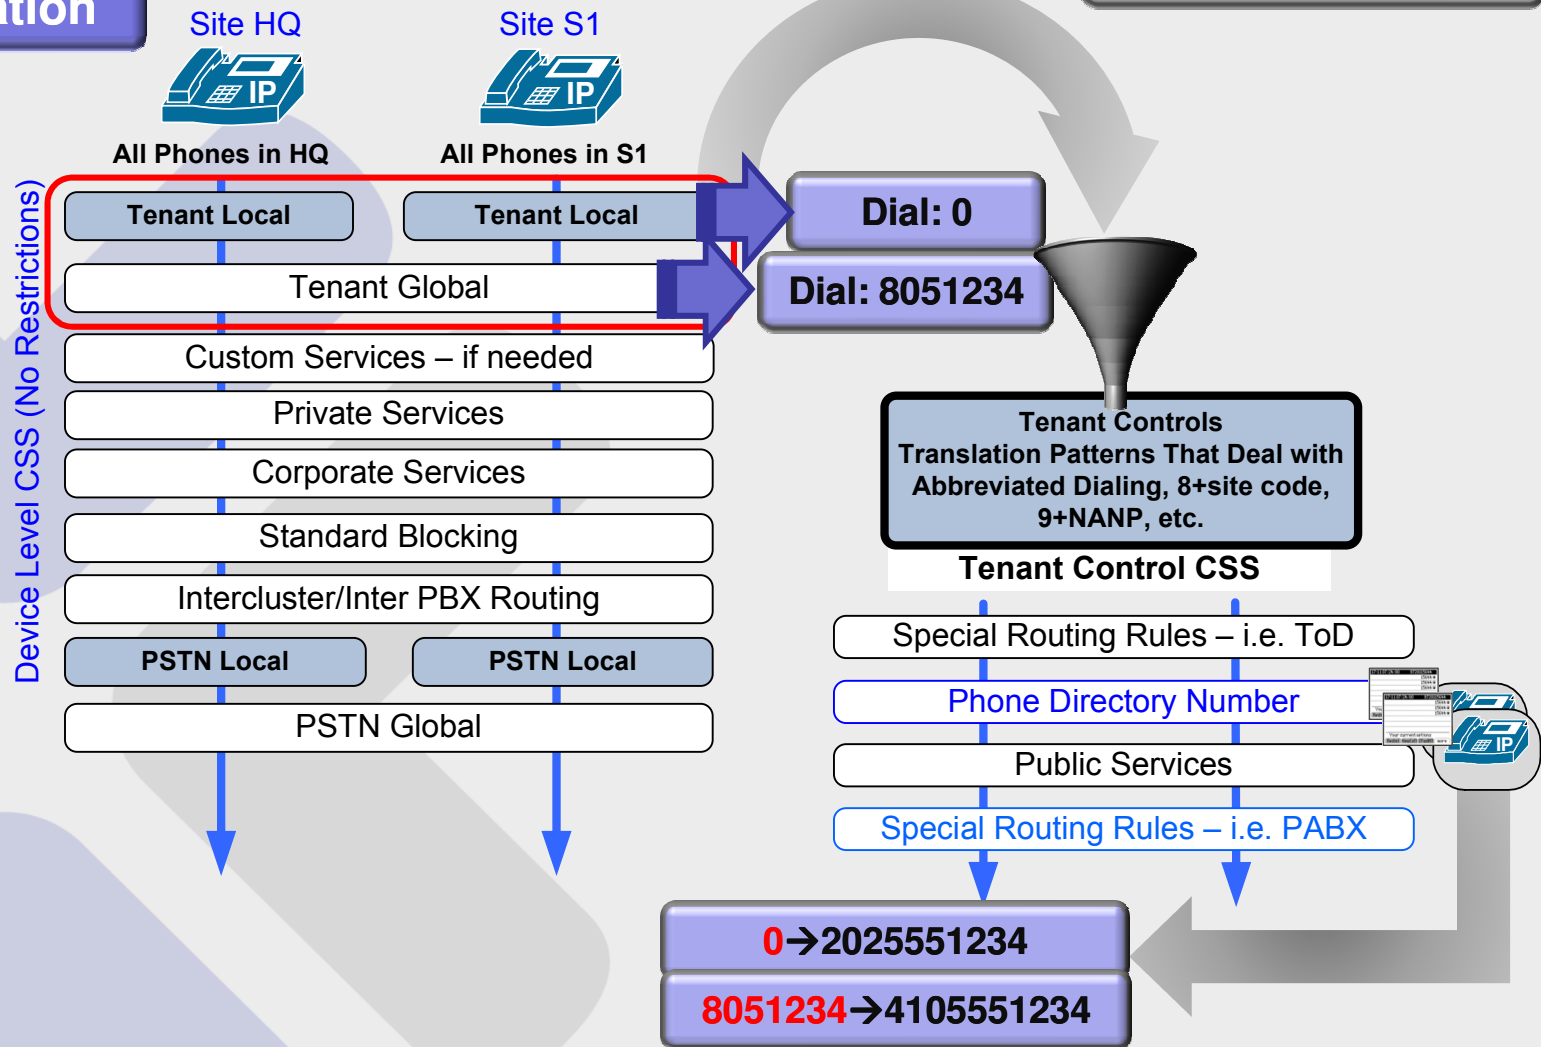

# Solution: Dial Plan Hierarchy

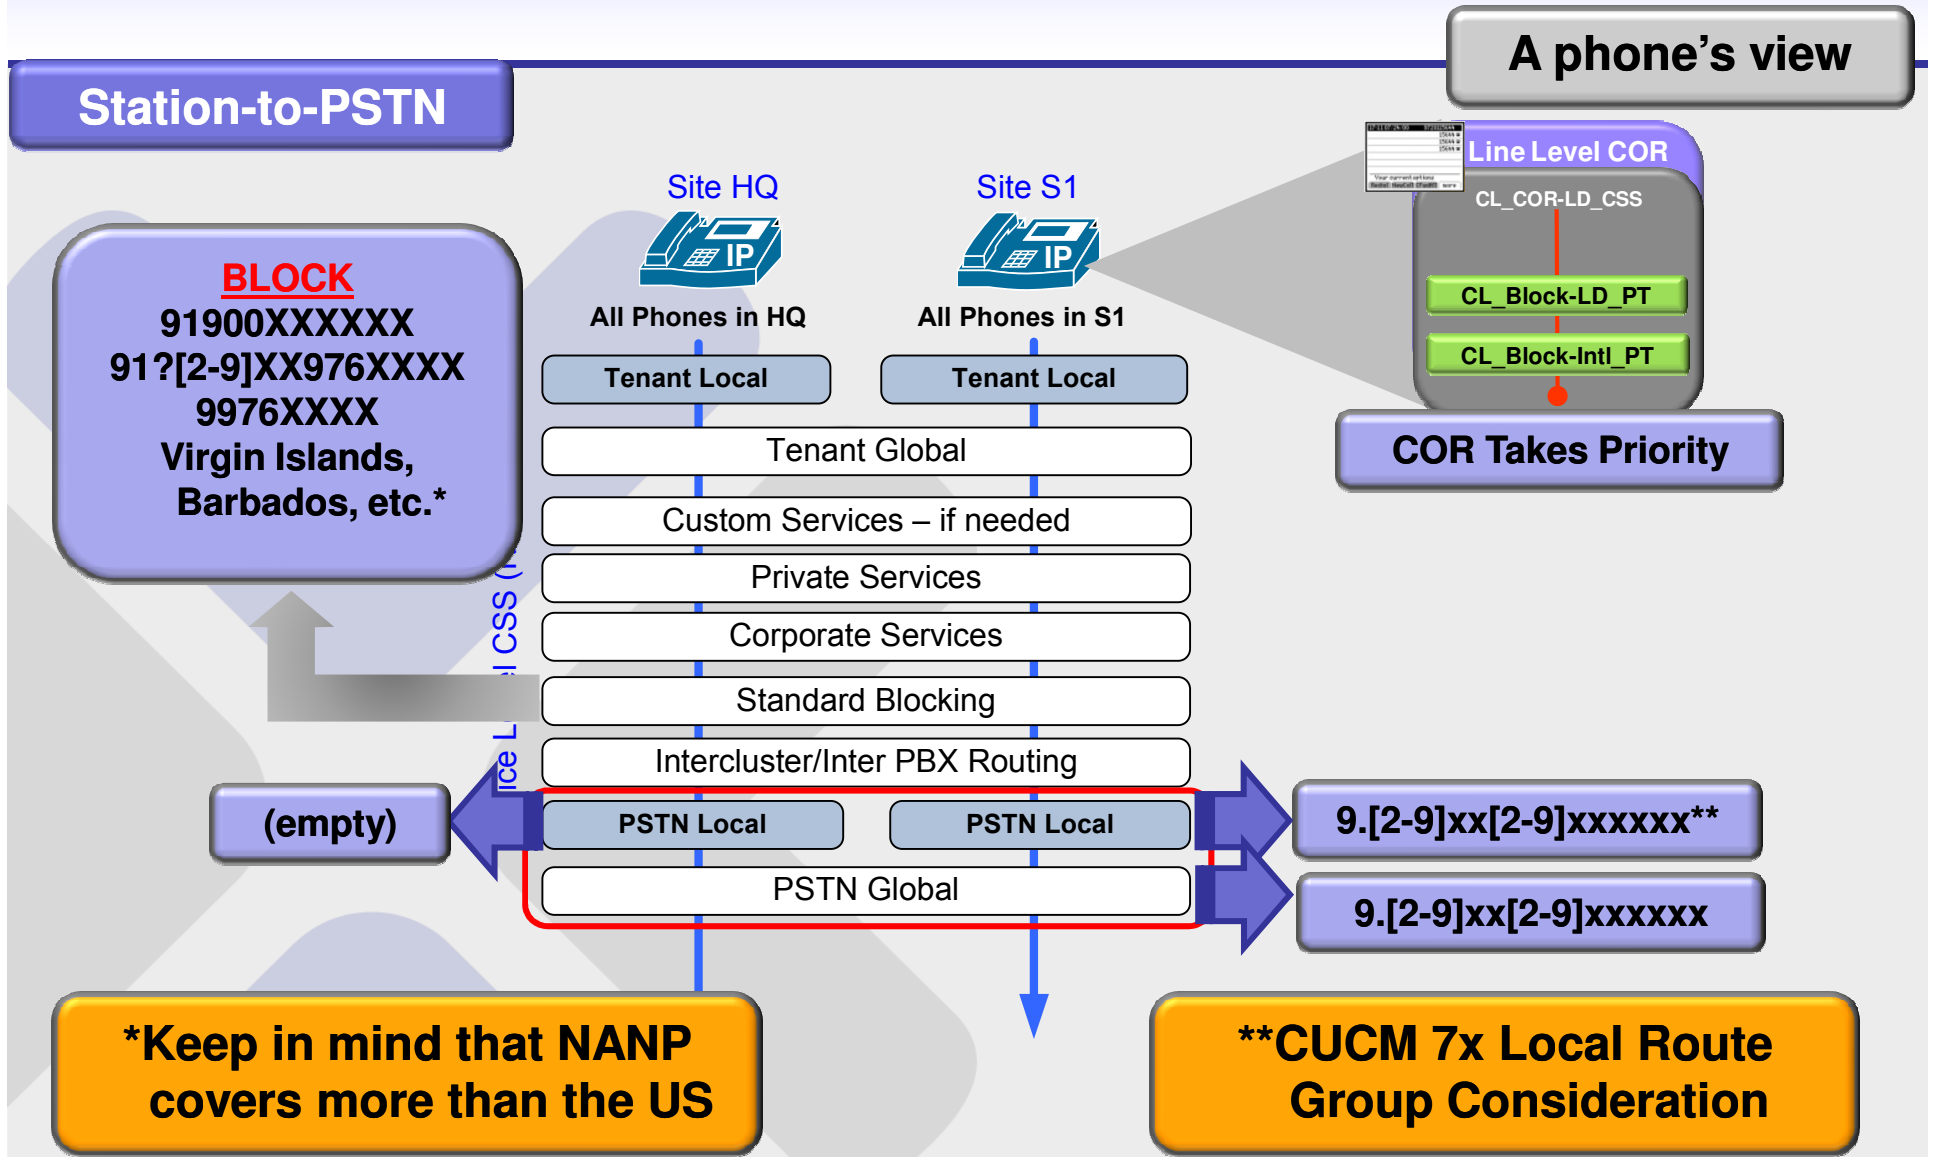

# Solution: Dial Plan Hierarchy

A phone's view

Station-to-Station

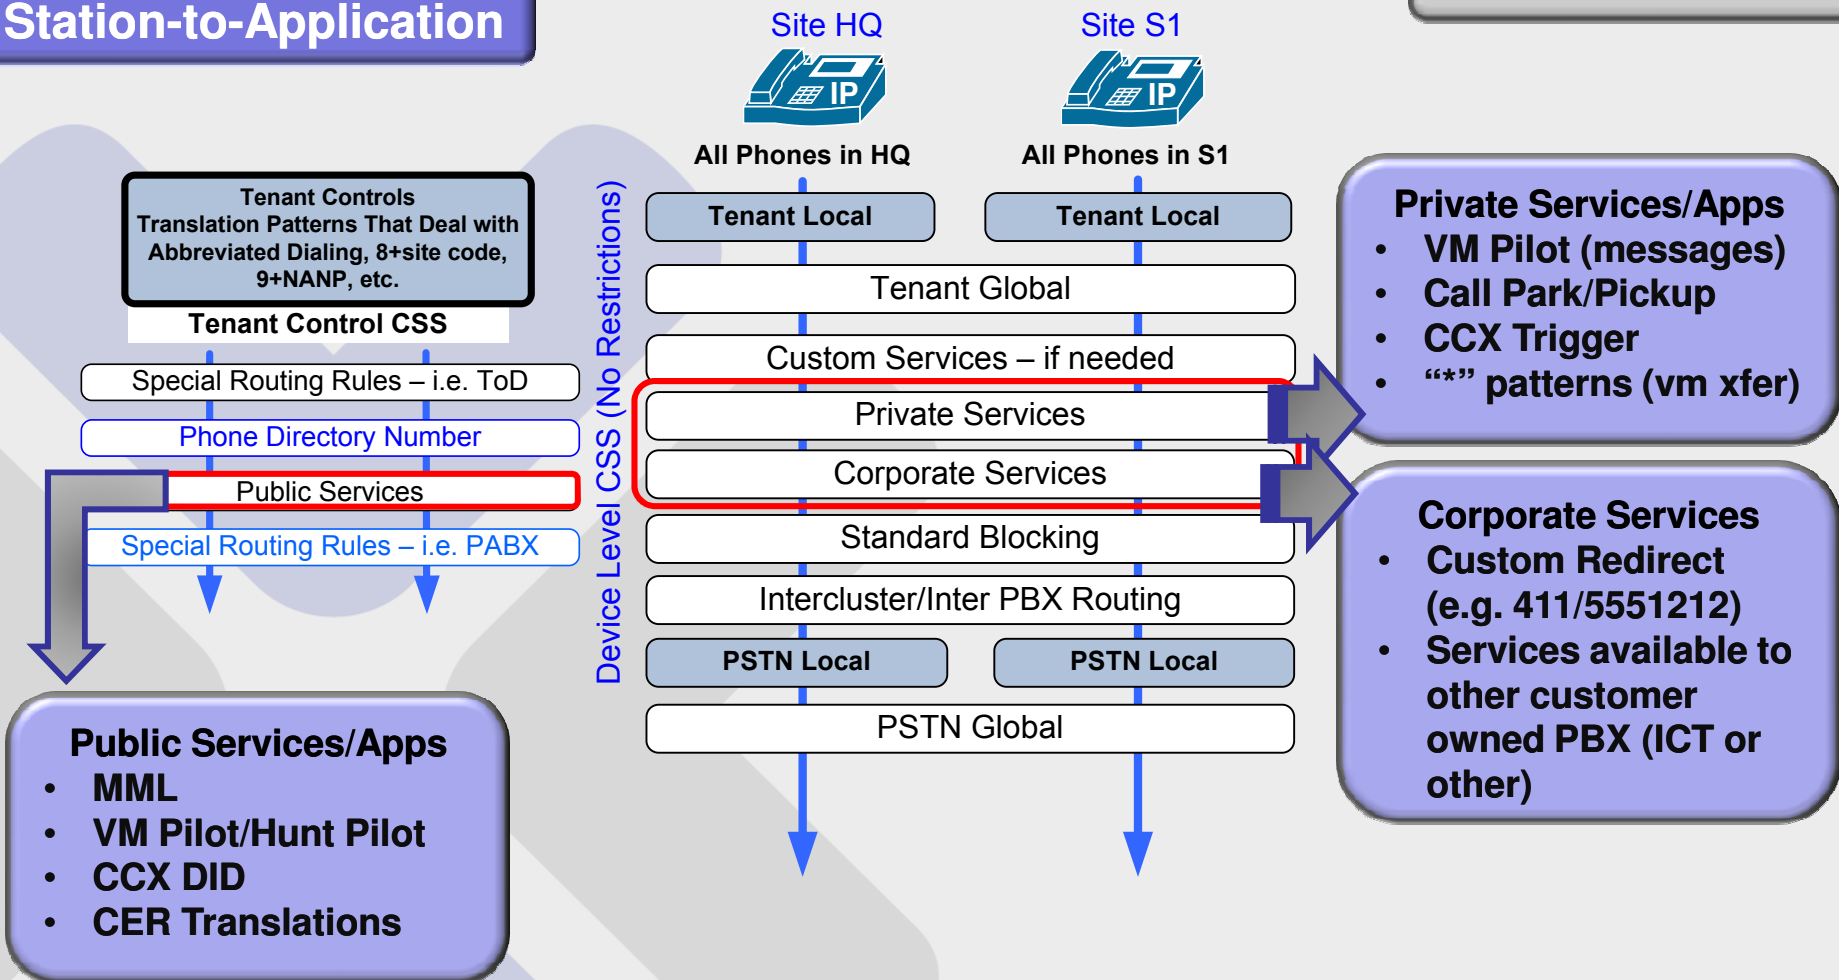

# Solution: Dial Plan Hierarchy

# Solution: Dial Plan Hierarchy

A phone's view

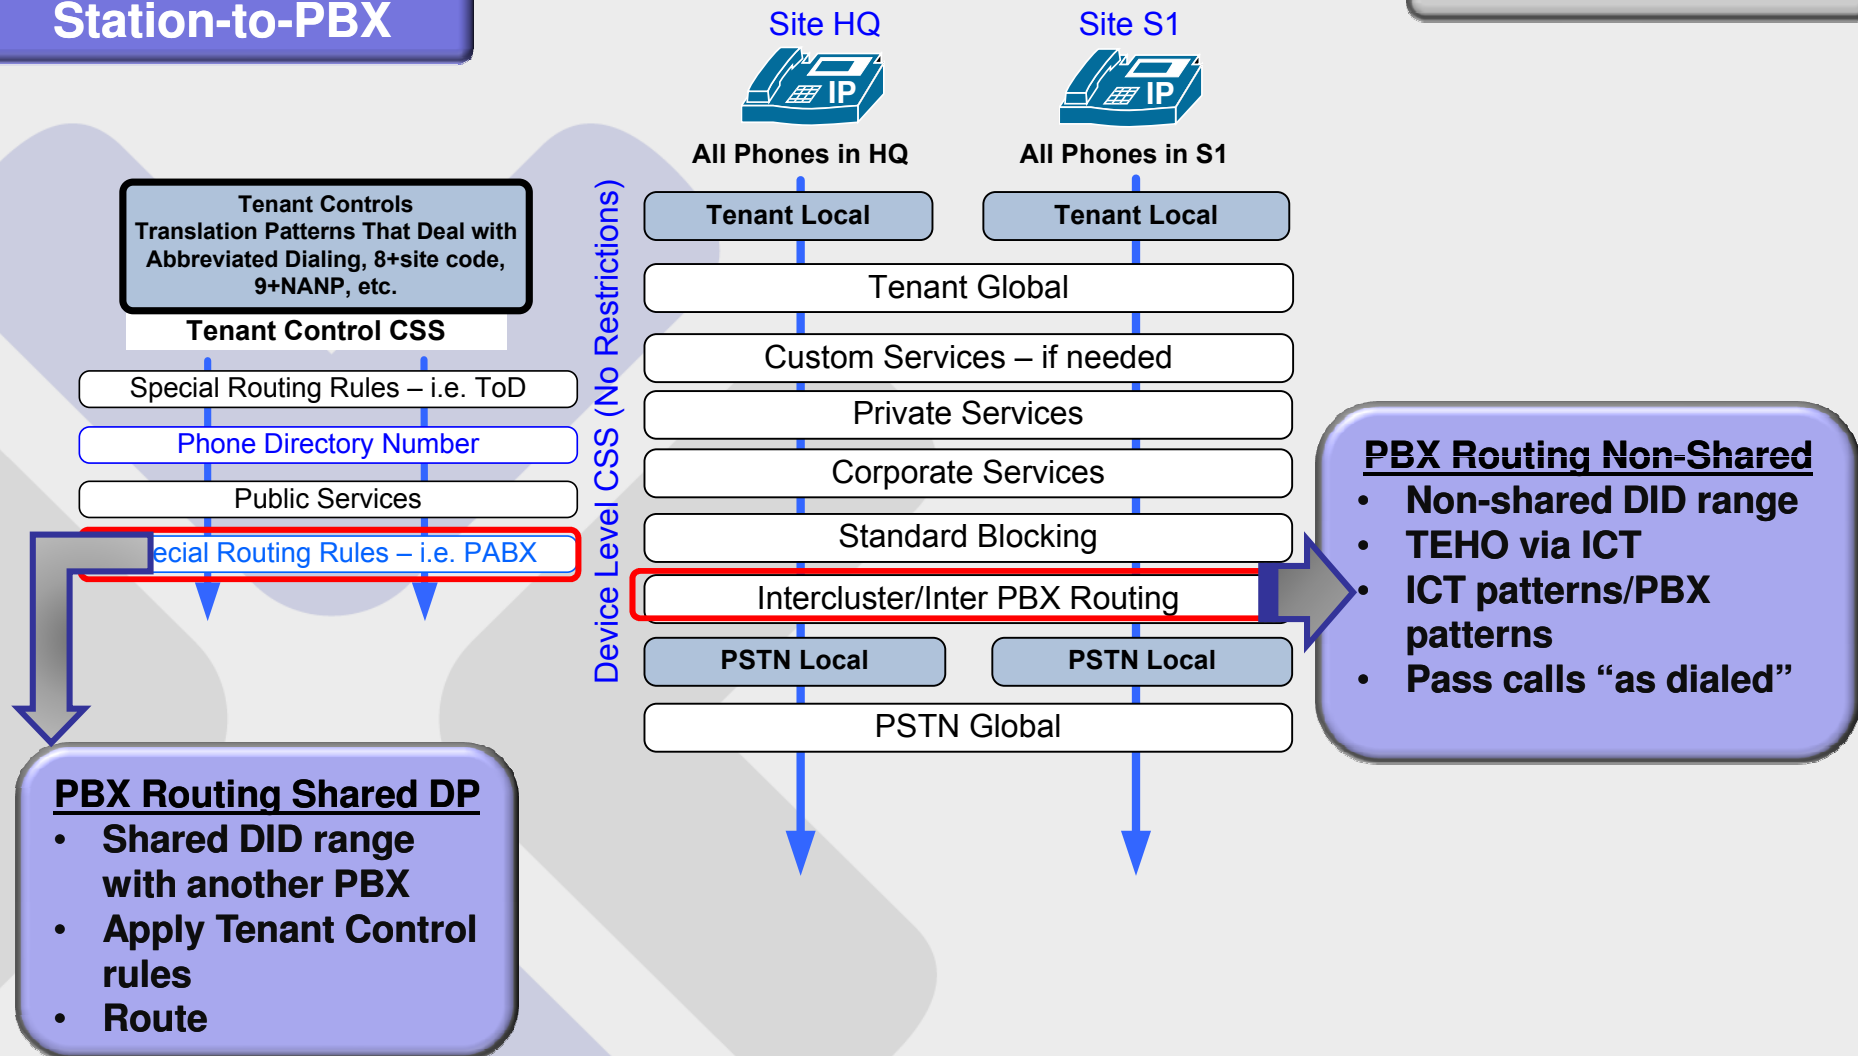

## Station-to-Application

# Solution: Dial Plan Hierarchy

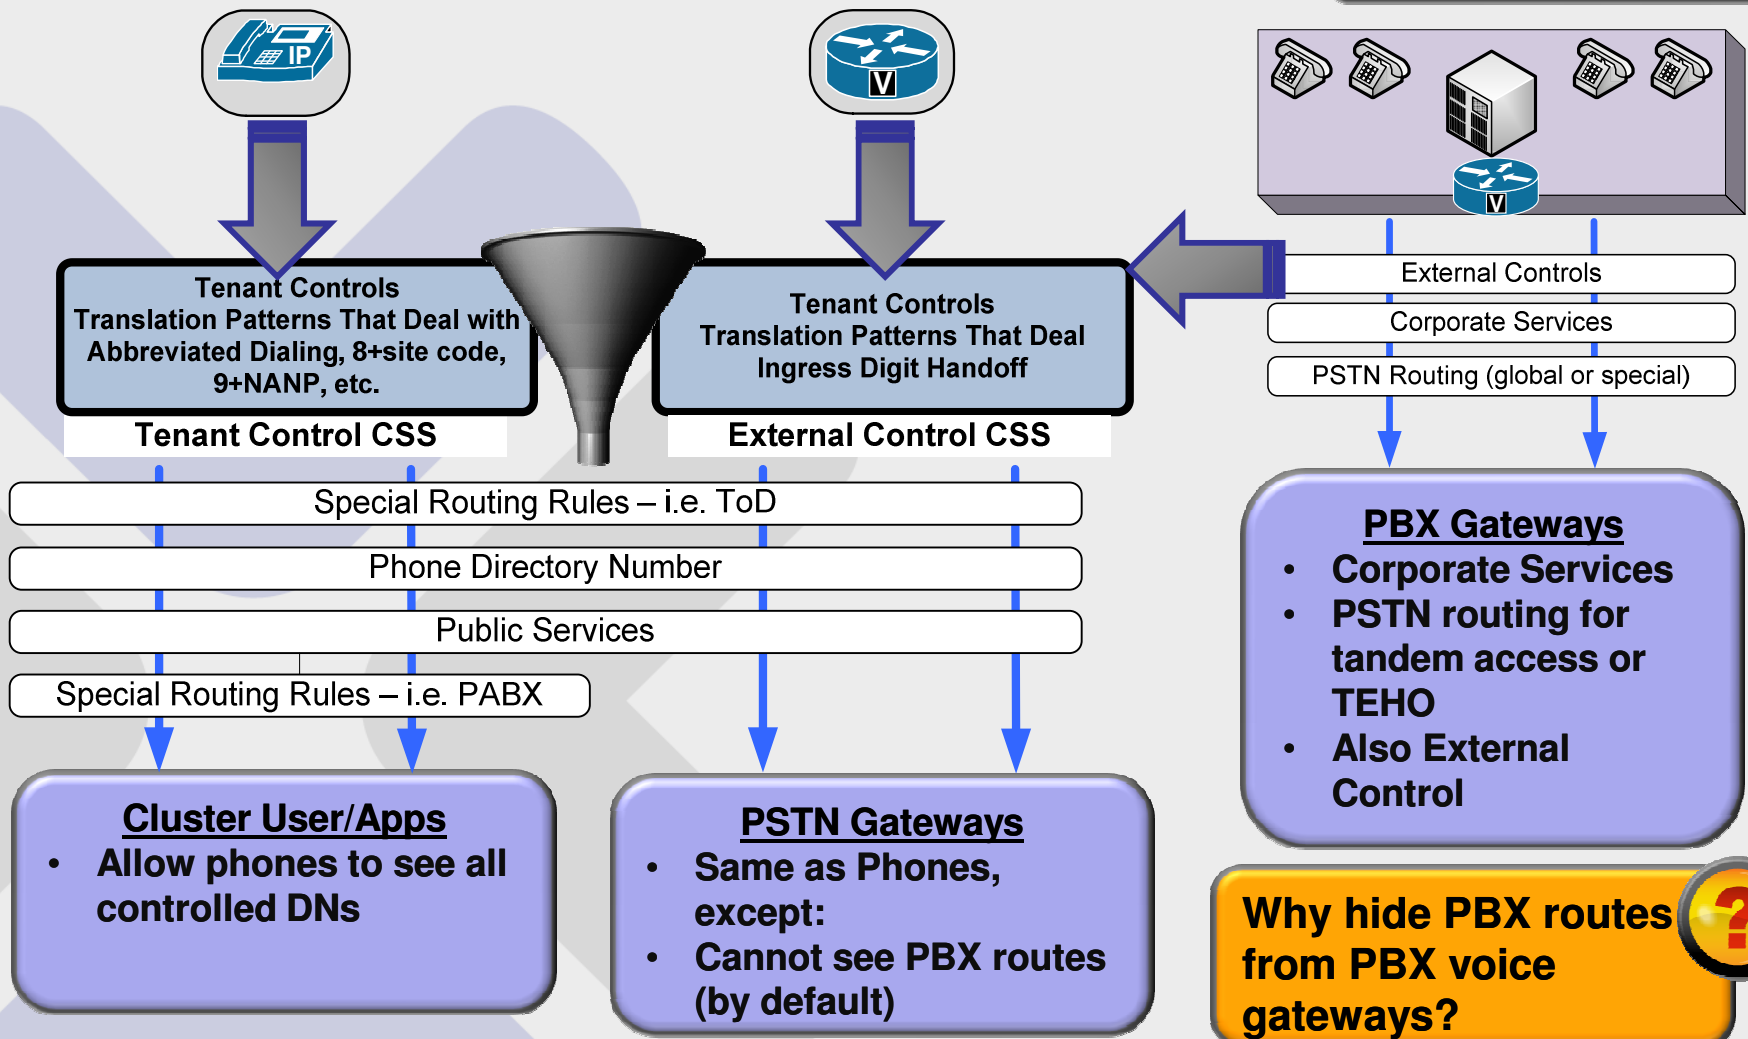

A phone's view

## Station-to-PBX

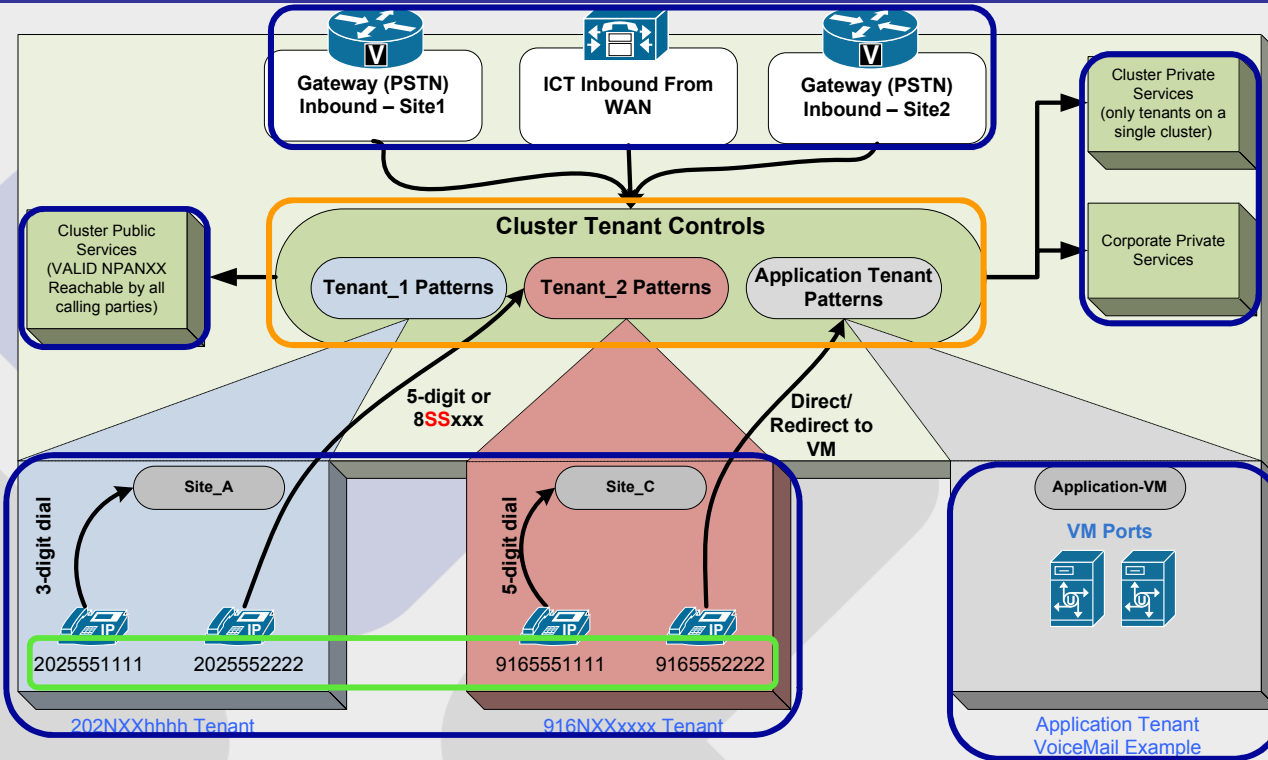

# Solution: Dial Plan Hierarchy

A GW view

# Solution: Dial Plan Hierarchy

We conceptually group our dial plan elements.  
**“Everything has a home.”**

We configure patterns to control access to/from a tenant

We leverage flat addressing for all applications and user stations

We define rules for handling calls flowing in, through, and out of the system and apply them consistently. In doing so, we find that the “core” dial plan stays consistent, only the numbers change.

# Dial Plan Changes in CUCM 7x

***Imagination is more important than knowledge.  
Knowledge is limited, imagination encircles the  
world***

# Dial Plan and CUCM 7x

- **Local Route Groups**

*The ability to dictate egress call routing behavior based on physical location of the calling device provides a key feature to the CUCM 7x new dial plan approach*

- **Support for E.164 “global” format with + dialing**

*CUCM 7x now supports “+” dialing from speed dials, applications, call lists, and directories. This provides CUCM with more options for integration and interoperability with applications like MS OCS and future position for end-to-end SIP carrier services*

- **Support for ingress/egress calling and called party transformations**

*Used in conjunction with “+” dialing (or without!), this feature allows for more granular control on localizing number presentation for ingress and egress calling*

# Dial Plan and CUCM 7x

## Local Route Groups

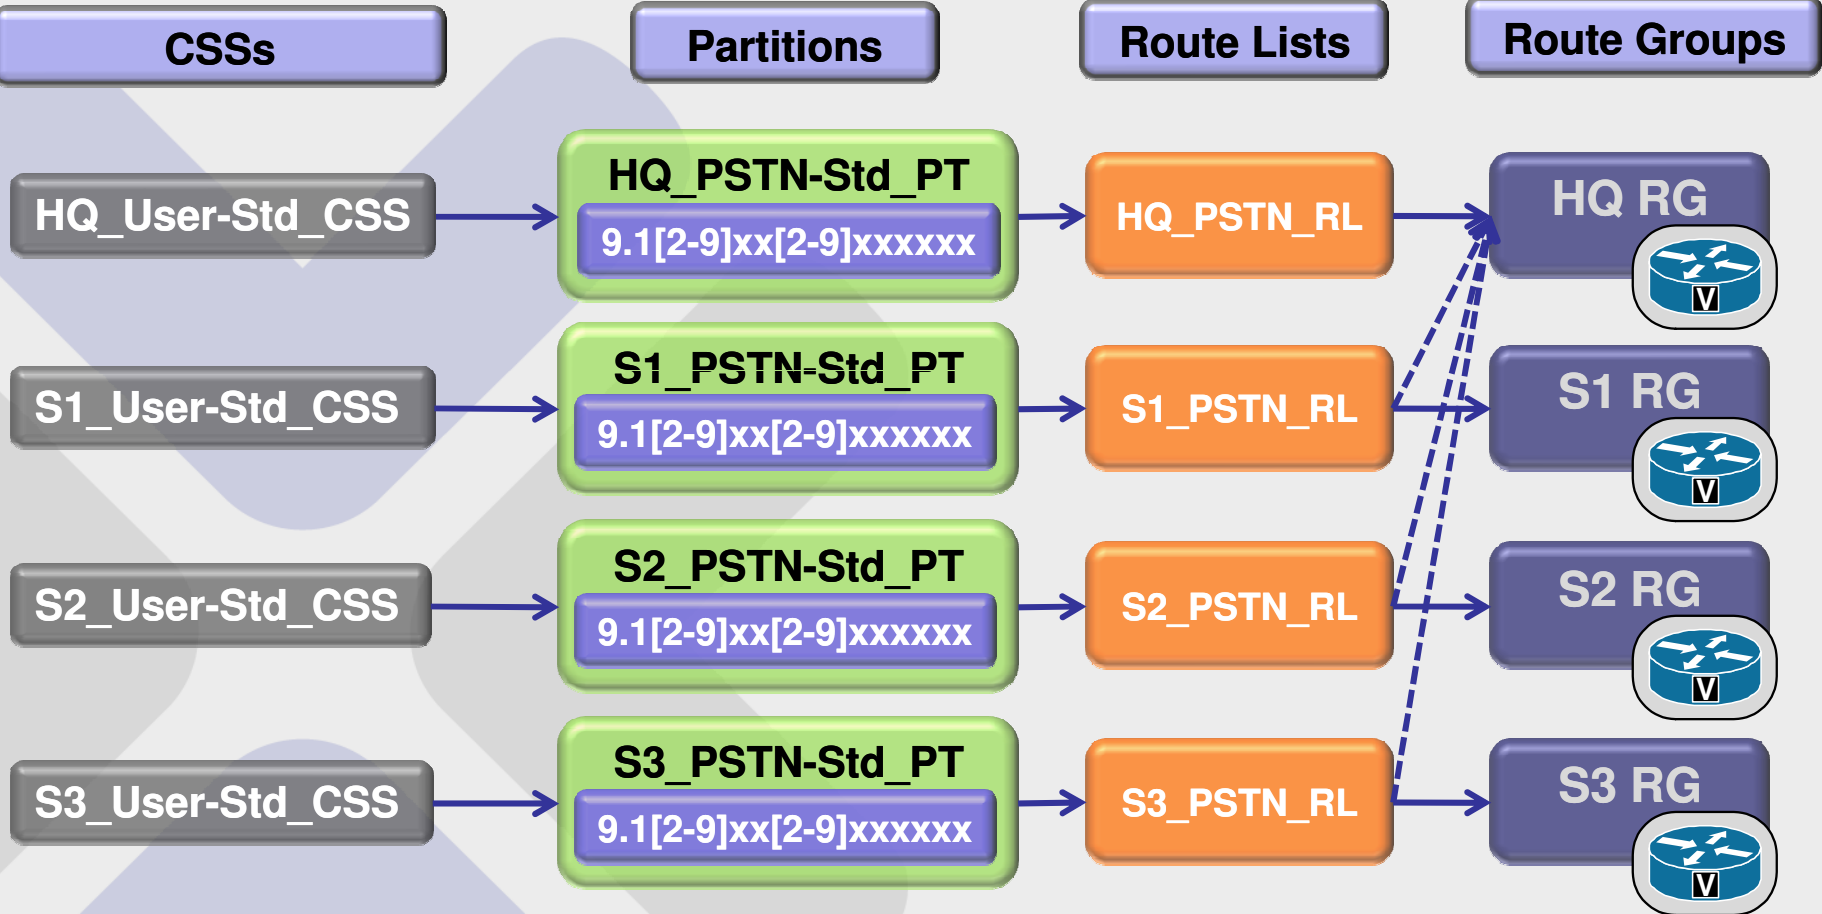

### The Concept

- **Leverage an existing configuration parameter (Device Pool) to attach site-specific call routing rules**
- **Add a new option to existing configuration parameter (Route List) that is a pointer to site-specific routing rules**
- **Objective: Endow a single route pattern with the ability to route calls to different locations based on the device placing the call**

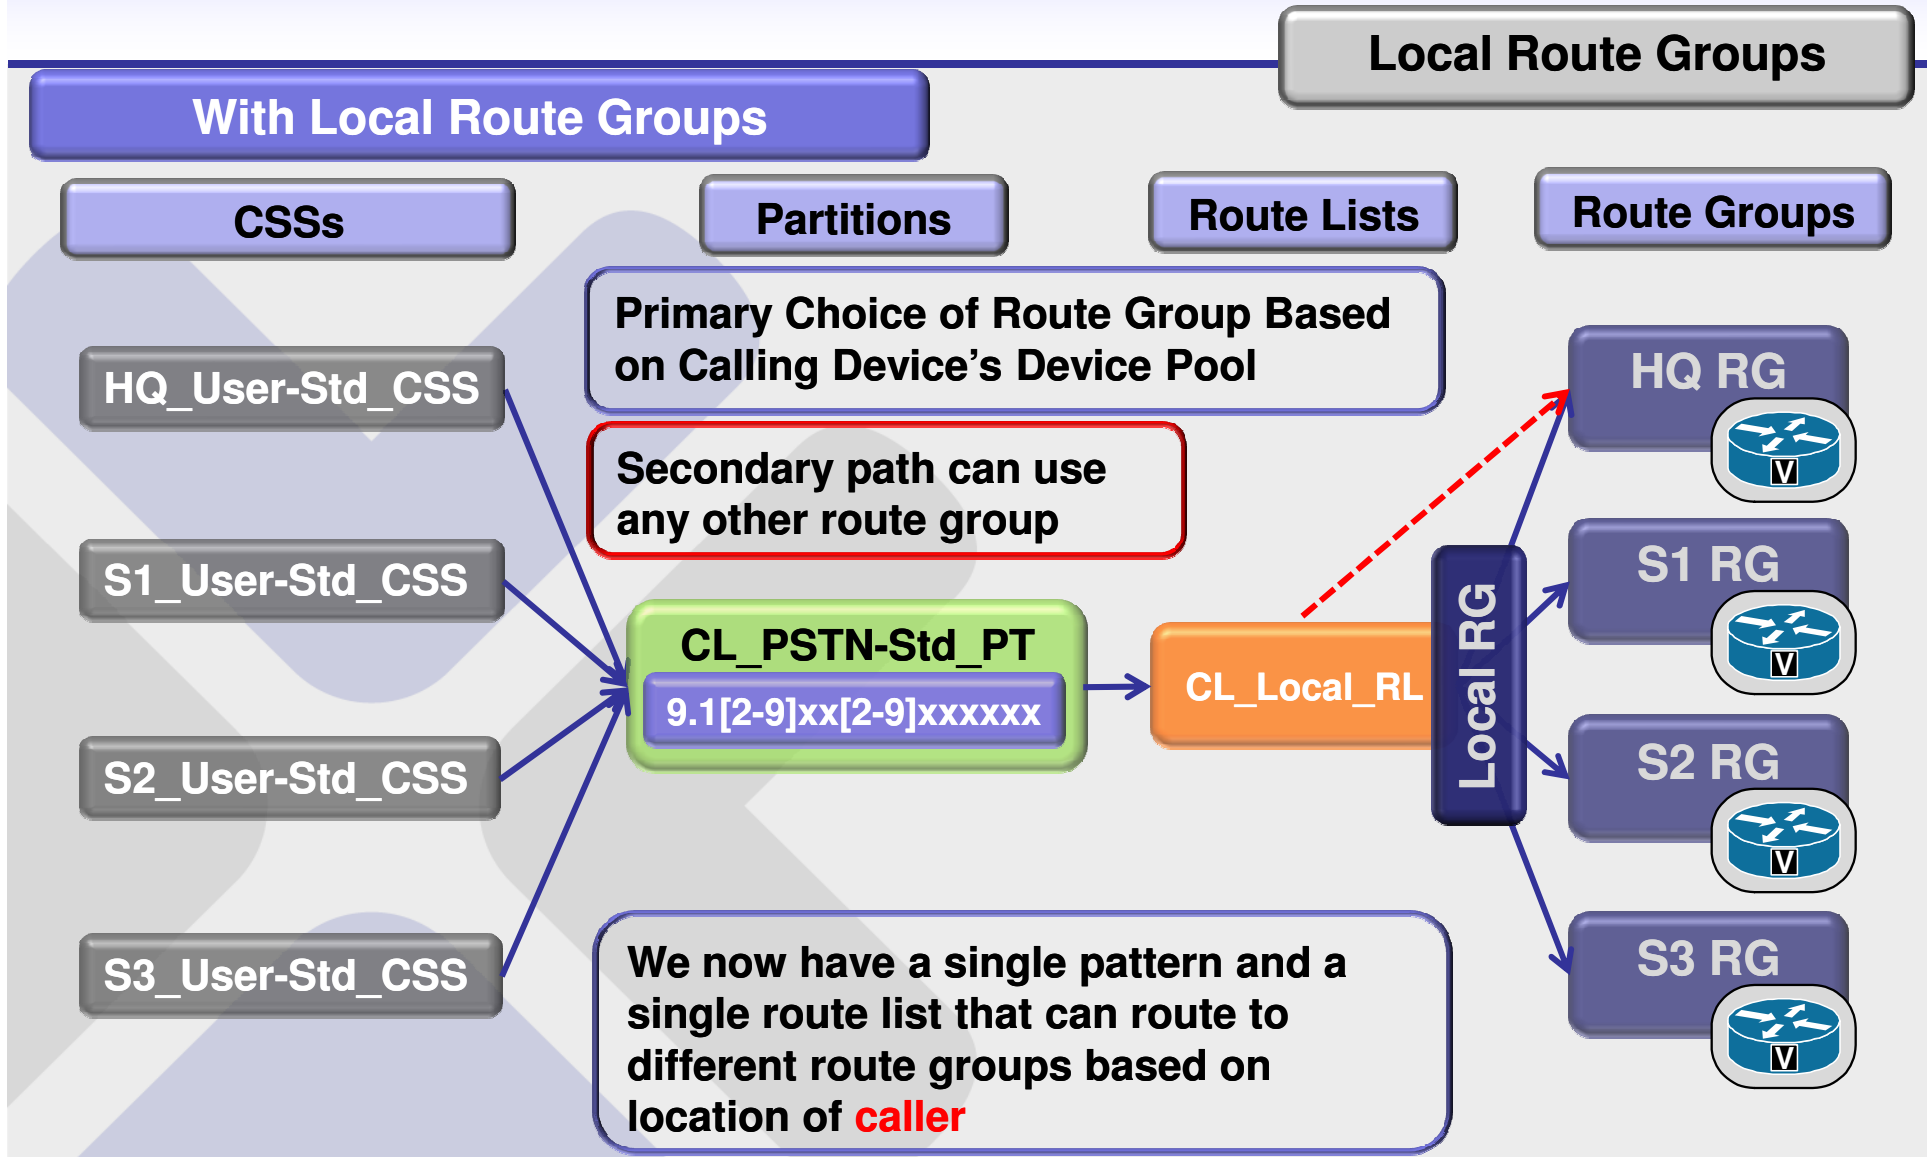

# Dial Plan and CUCM 7x

## Local Route Groups

### Without Local Route Groups

# Dial Plan and CUCM 7x

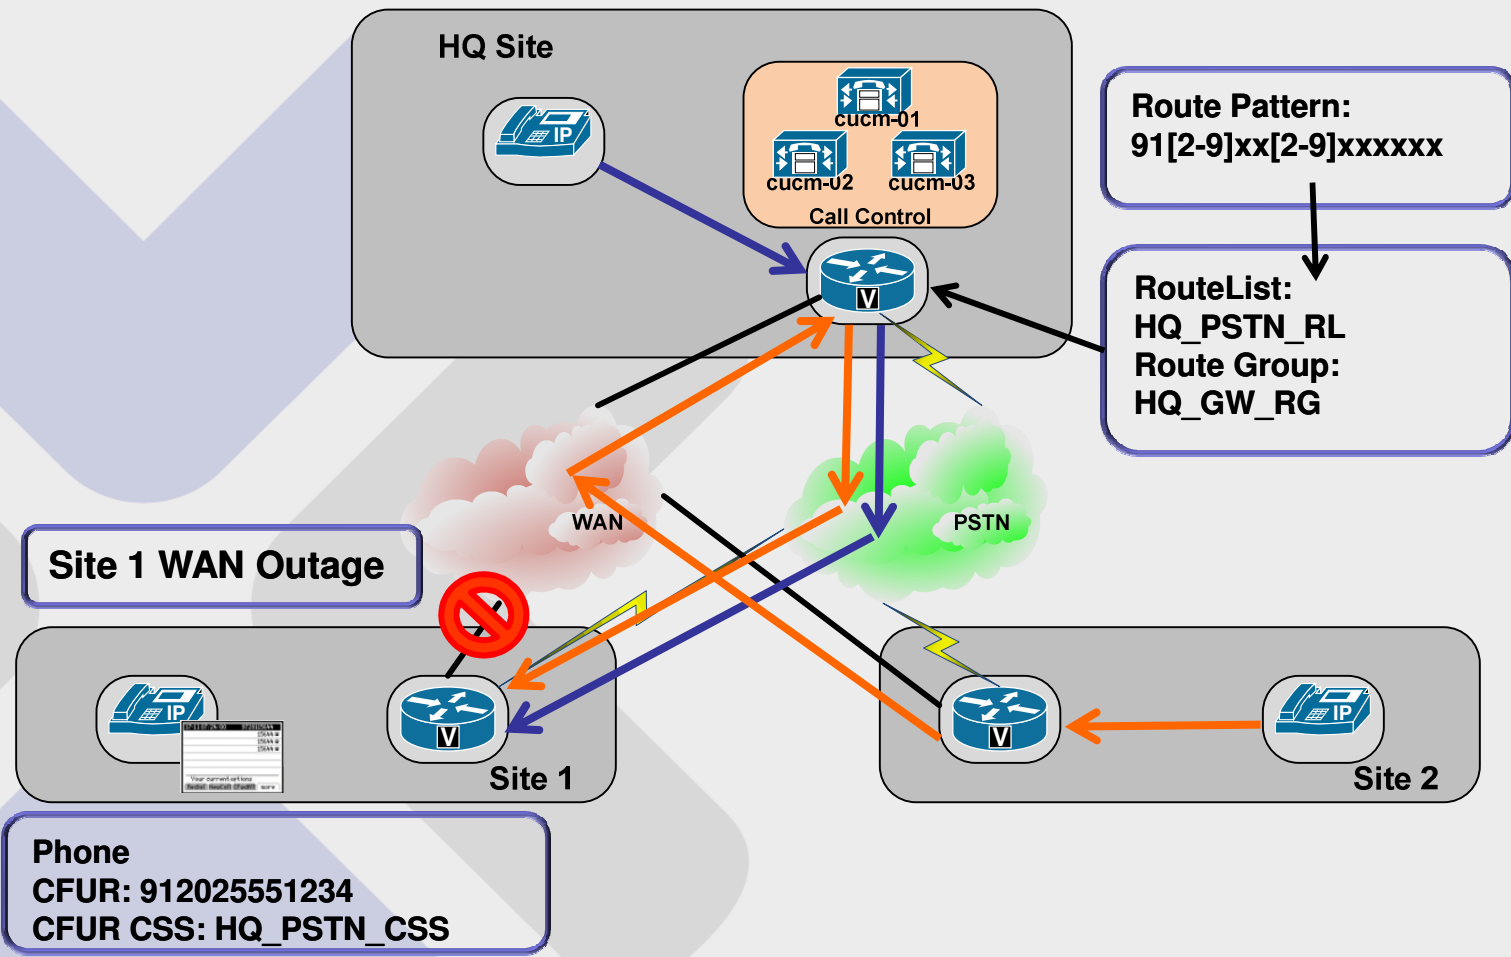

# Dial Plan and CUCM 7x

Local Route Groups

Example: CFUR

Without Local RG

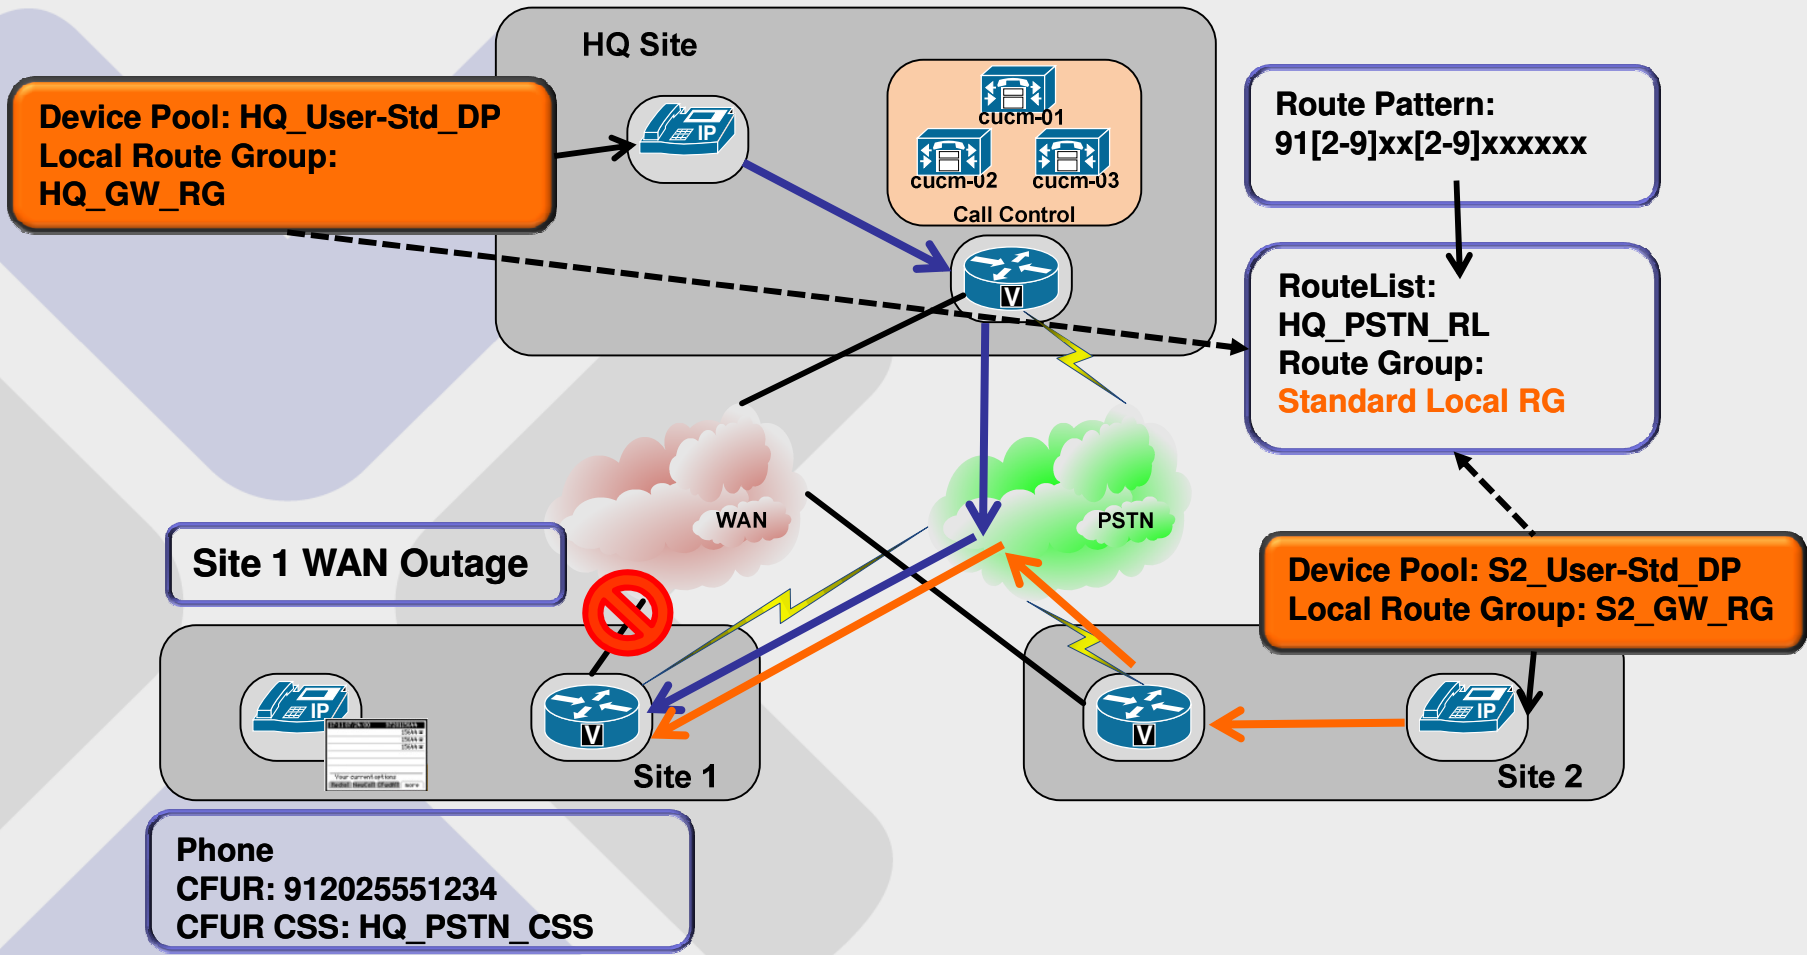

# Dial Plan and CUCM 7x

## Local Route Groups

Example: CFUR

With Local RG

# Dial Plan and CUCM 7x

## Local Route Groups

### More Examples

#### Call Forwarding – In general

Any forwarding that allows off net dialing can take advantage of local route groups

#### CER Failure Scenario

Primary and Secondary CER server offline

- Without LRG: you can only have one destination → one path (i.e. one PSAP)
- With LRG: you can have one destination → site-specific path\*

#### Tail End Hop Off (TEHO) with Local Site Failover

This is possible with or without LRG  
**However**, with LRG you can minimize the number of route patterns that are required

\*Actually, in CM 4.1 there is a workaround available

# Dial Plan and CUCM 7x

Globalized Format Dialing

## ITU-T E.164 Recommendation

- **Defines international public telecommunications numbering plan for PSTN (and other networks)**
- **Maximum 15 digits**
- **E.164 numbers start with a country code and no localized prefix**
  - **United States country code is “+1”**
  - **France country code is “+33”**
- **E.164 digits may be used in call setup if the ingress network/switch accepts the digit format**
  - **Localized international dialing prefixes still required for many places (e.g. 011 in North America)**
  - **Cisco Unified Communications Manager 7x accepts the E.164 format**

# Dial Plan and CUCM 7x

## Globalized Format Dialing

### The “+” Dialing Concept

- Users are not asked to enter “+” digit when dialing and most Cisco phones don’t support “+” digit entry (7921 and 7925 do)
- Applications like “Click-to-Call” and CUCIMOC\* or directories like Corporate Directory, speed dials, Missed Calls, etc. can use “+” dialing natively
- From an egress point of view:
  - “globalize” dialed digit strings *prior* to routing decision
  - On egress, localize the pattern to conform with PSTN
- From an ingress point of view:
  - “localize” ingress patterns *prior* to routing decision

\*Cisco UC Integration for Microsoft Office Communicator

# Dial Plan and CUCM 7x

## Globalized Format Dialing

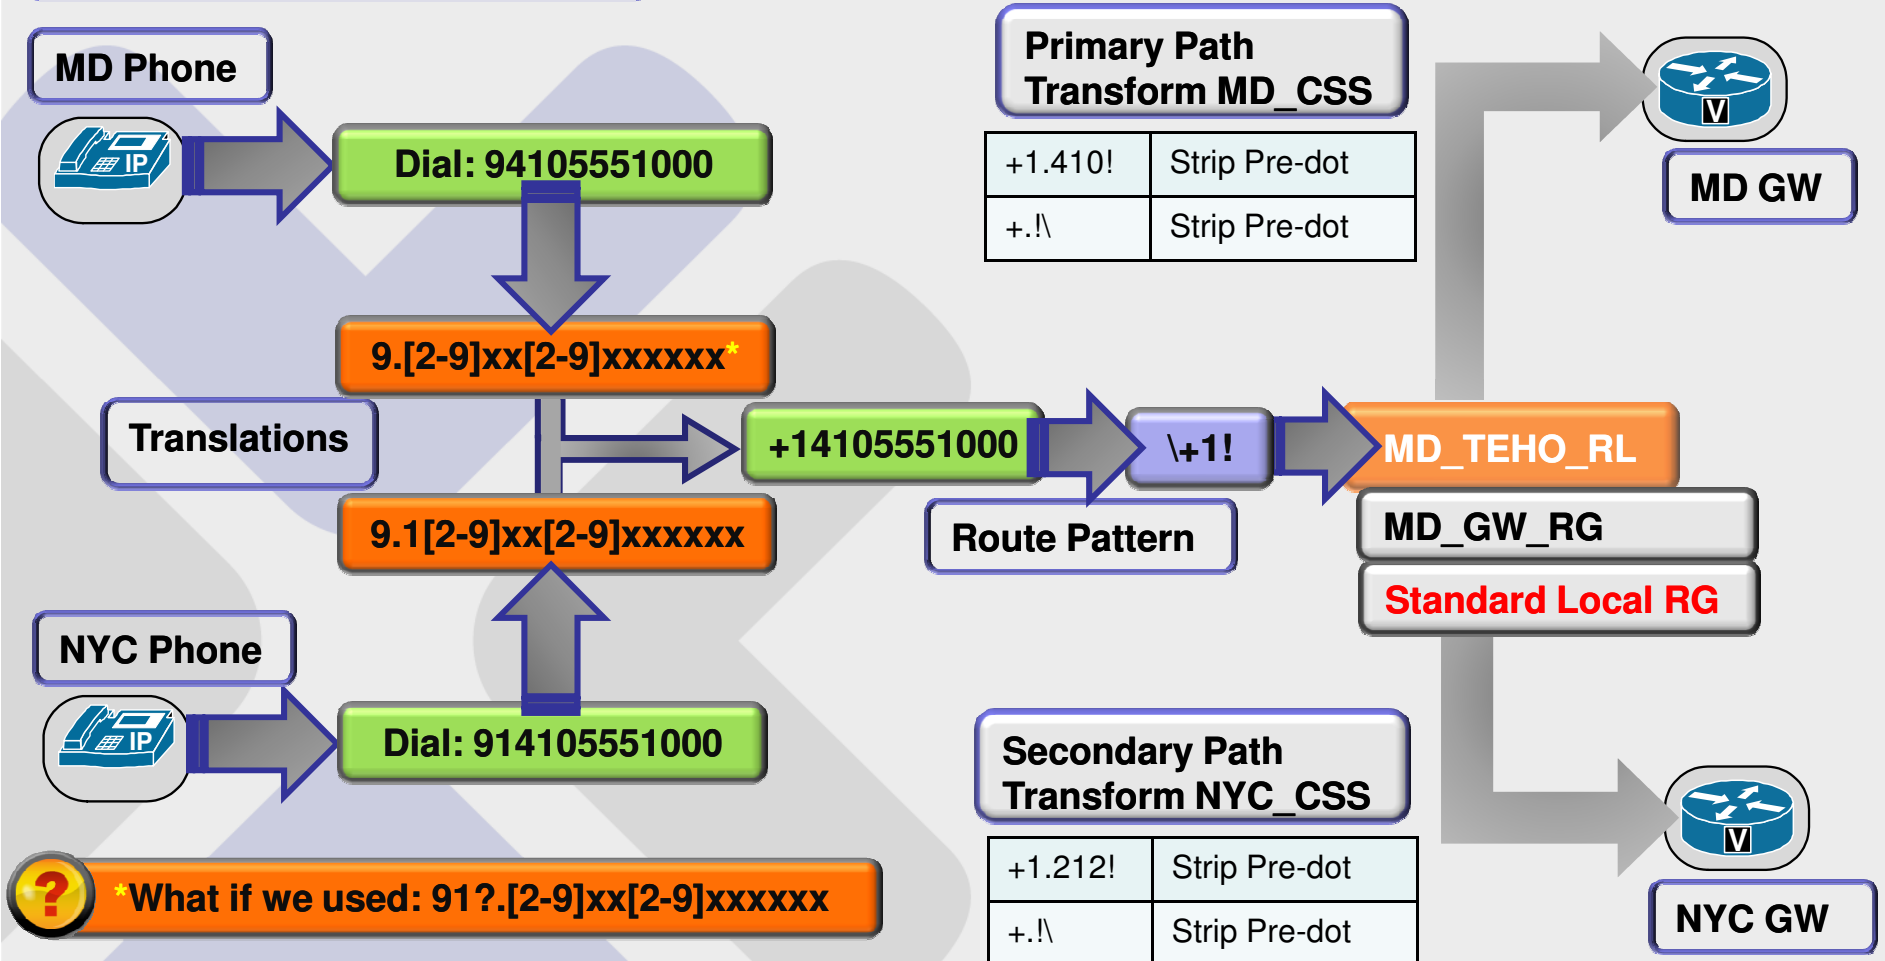

### Transformation Patterns

- **Localized call routing prefixes for National, International, etc. are still required (i.e. no “+” dialing in ISDN Q.931 call setup)**
- **Calling number format presented on a phone are typically dictated by the end user**
- **Number format for calls presented to the gateway for routing off net are dictated by the gateway and network routing the call**
- **A mechanism is required to handle “transformation” of the E.164 “global” format to relevant localized patterns**

# Dial Plan and CUCM 7x

## Globalized Format Dialing

### An Example: Egress

# Dial Plan and CUCM 7x

## Globalized Format Dialing

### An Example: Ingress

PSTN Caller

CLID: 2025551234

DC GW

### Transform Calling Party Ingress

National	Prefix +1
International	Prefix +
Subscriber	Prefix +1202

DC Phone

Display	5551234
Call Back	+12025551234

CA Phone

Display	2025551234
Call Back	+12025551234

Germany Phone

Display	+12025551234
Call Back	+12025551234

DC Devices Transform -In CSS

+1202.!	Strip Pre-dot
+1.! \	Strip Pre-dot
+!	

**Globalize on Ingress (GW) and Localize on Egress (Phone). The idea is the user gets the display they are used to and the ability to call back without "Edit Dial"**

# Dial Plan and CUCM 7x

## Globalized Format Dialing

### Possible Benefits

#### Emergency Calling

Corporate wide emergency number that routes to PSAP number that is localized to caller

#### Automated Alternate Routing (AAR)

- AAR calls placed to global numbers removes need for multiple AAR groups
- Single pattern (\+.) sufficient for all phones
- Single AAR CSS for all phones

#### Tail End Hop Off (TEHO) with Local Site Failover

- Even more powerful than LRG alone
- Can leverage \+ dialing and transformations to minimize number of route patterns required

**Thank you for your time!**

# Q&A

**NetCraftsmen UC Blog:**

**<http://www.netcraftsmen.net/resources/blogs>**
